Re: Radford Army Ammunition Plant, Va.
Review of Army's Final RCRA Facility Investigation Report for
Solid Waste Management Units (SWMUs) 35, 37, 38, and
Area of Concern (AOC) Q

Dear Mr. McKenna and Ms. Holt:

The U.S. Environmental Protection Agency (EPA) and Virginia Department of Environmental Quality (VDEQ) have reviewed the U.S. Army's (Army's) September 2010 Final RCRA Facility Investigation (RFI) Report for Solid Waste Management Units (SWMUs) 35, 37, 38, and Area of Concern (AOC) Q, located at the Radford Army Ammunition Plant (RFAAP) in Radford, Virginia. Based upon our review, the report is approved, and in accordance with Part II. (E) (5) of RFAAP's Corrective Action Permit, it can now be considered final.

If you have any questions, please call me at 215-814-3413. Thanks.

Sincerely,

William Geiger
RCRA Project Manager
Office of Remediation (3LC20)

Subject: With Certification, Solid Waste Management Units 35, 37, 38, and Area of Concern Q (RAAP-010) RCRA Facility Investigation Report, Final September 2010
EPA ID# VA1 210020730

Dear Mr. Geiger and Mr. Cutler:

Enclosed is the certification for the subject document that was sent to you on September 20, 2010. Also enclosed is the 20 September 2010 transmittal email.

Please coordinate with and provide any questions or comments to myself at (540) 639-8658, Jerry Redder ATK staff (540) 639-7536 or Jim McKenna, ACO Staff (540) 731-5782.

Sincerely,

P.W. Holt, Environmental Manager

Response to Comments (November 12, 2009)
Comments on the *Draft Solid Waste Management Units 35, 37, 38, and Area of Concern Q (RAAP-10) RCRA Facility Investigation Report* for the Radford Army Ammunition Plant (RFAAP) located in Radford, Virginia, dated July 2009 (RFI Report). Received October 2, 2009.

GENERAL COMMENTS

1. The RFI Report concludes that, on the basis of the human health risk assessment (HHRA) and ecological risk assessment results, no further action is recommended for the sites. However, calcium sulfate sludge is present at the sites. Although soil and groundwater media are not currently impacted by the sludge at unacceptable levels, the constituents in the sludge itself do not appear to have been evaluated in the risk assessments. Table 2-4, Summary of Historical Analytical Data for Sediment/Soil Samples Collected at SWMU [Solid Waste Management Unit] 35, show that lead concentrations in two sludge samples collected from SWMU 35 exceeded 50,000 milligrams per kilogram (mg/kg), well above the residential and industrial action levels (400 mg/kg and 750 mg/kg, respectively). Arsenic, chromium, mercury, nickel, silver, dinitrotoluene mixture, and phenanthrene also exceeded applicable screening criteria in sludge samples 35SE1 and 35SE2, but it does not appear that these samples were considered in the evaluation of risk. Please revise the RFI to provide further justification that the calcium sulfate sludge at the sites, and specifically at SWMU 35, will not present an unacceptable level of risk to receptors. The RFI Report should clearly substantiate that an ongoing release to groundwater from the sludge itself is not possible, in consideration of the high levels of lead and other constituents detected in historical sludge samples. Also, what is the status of the remaining sludge as a waste? Are there any regulatory ramifications with leaving it in place?

   Response: Prior to the RFI, historical soil analytical data (1990 and 1992) were considered screening level data and excluded from the risk assessment given the age of the data, the use of non SW-846 analytical methods, the lack of available data validation reports/information, and the availability of sufficient newer validated RFI data to more appropriately characterize conditions at the site. It should be noted that a results transcription error occurred for the sample result 35SE2 in Table 2-4. The lead concentration for 35SE2 should be >5,000 mg/kg rather than the >50,000 mg/kg shown in the table. Table 2-4 will be revised accordingly,

   Sample results for the RFI (including SSP) did not confirm the presence of elevated lead levels in calcium sludge detected in the two samples collected from SWMU 35 in 1990. Lead samples results for 13 of 15 RFI samples of calcium sulfate sludge were below 400 mg/kg (17 to 290 mg/kg), with the remaining two sample results at 530 and 750 mg/kg, respectively. The mean concentration of lead detected in the RFI calcium sulfate samples was 198 mg/kg.

The risk assessments for each site evaluated the potential risk associated with current/future use of the sites as the drying beds are currently configured using surface soil data (SSP/RFI data from 0 to 1 ft bgs), which includes calcium sulfate sludge present in the drying beds. As discussed in Section 6.7 of the RFI Report, the results of the human health risk assessments for SWMUs 35, 37, and 38/Q did not indicate a requirement for future action for the site on the basis of human health; calculated site-related cancer risk and hazards were within USEPA target ranges for each of the receptors evaluated when considering background, target organs, and frequency of detection, and site-specific conditions.

Sections 4.1.2, 4.3.2, and 4.5.2 of the RFI Report present a detailed nature and extent assessment for each chemical of potential concern (COPC) at SWMUs 35, 37, and 38/Q including an assessment of COPC leaching to underlying soil and groundwater. As presented in these sections, evidence of appreciable leaching of COPCs from sludge to underlying subsurface soil or groundwater has not been observed at the sites. Figures 4-1, 4-2, 4-4, 4-5, 4-7, and 4-8 illustrate the vertical attenuation of concentrations from "A" level samples of sludge in the drying bed to "B" level samples of soil immediately below the sludge.

Sections 4.1.3, 4.3.3, 4.5.3, and 5.1.4 of the RFI Report present detailed soil-to-groundwater migration assessments for identified COPCs and concluded that appreciable leaching of COPCs from calcium sulfate sludge to subsurface soil or groundwater has not occurred at the site and is unlikely to occur in the future given the following:

- The results of RFI sampling indicated low concentrations of COPCs in calcium sulfate sludge, which are unlikely to represent a significant source for leaching to subsurface soil or groundwater. The neutral pH and higher organic content of the sludge will reduce the mobility and leachability of lead, chromium, and organic COPCs present in this material.
- Appreciable leaching of COPCs from sludge to underlying subsurface soil and groundwater has not been observed at the sites more than 55 years after waste management activities began and more than 25 years after waste management activities had ceased at the site;
- The limited organic COPCs detected in calcium sulfate sludge were not detected in groundwater samples collected at the sites;
- The primary inorganic COPCs detected in calcium sulfate sludge, lead and chromium, were not detected at dissolved concentrations above their adjusted risk-based screening levels.

The calcium sulfate sludge present in the drying beds is solid waste as defined in 40 CFR §261.2 but is not a listed hazardous waste or characteristic hazardous waste. Hazardous waste characteristics of the sludge were assessed by analyzing one composite sample of sludge from each drying bed for corrosivity (pH) and toxicity (full toxicity characteristic leaching procedure [TCLP] analysis).

Reactivity of the sludge was evaluated by analyzing discrete sludge samples for explosives content by SW-846 Methods 8330 and 8332; selected sludge samples were also analyzed for cyanide. Waste characterization results are presented in the attached table and summarized below:

- Sludge samples had pH levels in the range of 7.5 to 7.9 and therefore this material does not exhibit the characteristic of corrosivity as defined in 40 CFR §261.22;
- TCLP levels of sludge samples are below regulatory limits specified in 40 CRF § 261.24, and therefore this material does not exhibit the characteristic of toxicity;
- TCLP detections are limited to low levels of barium, silver, and chromium (one sample) at levels approximately three orders of magnitude below regulatory limits; and
- Explosives and cyanide are present in some of the sludge samples at low concentrations below human health risk-based screening levels and therefore this material does not exhibit the characteristic of reactivity as defined in 40 CFR §261.23.

Specific regulatory ramifications have not been identified for leaving the material in place given that the material is not a hazardous waste, does not contain hazardous constituents at levels that may pose a risk to human health or the environment, and does not represent a source area for future leaching to subsurface soil or groundwater at levels of concern.

2. There appear to be a few deviations from the work proposed in the *Final Work Plan Addendum 020 for RCRA Facility Investigation at Solid Waste Management Units 35, 37, 38, and Area of Concern Q (Work Plan Addendum 020)*, dated October 2007, that are not addressed in the RFI Report. The following deviations were noted:

   - Section 3.6.1.1, Inside Drying Bed Areas, and Section 3.6.1.2, Outside Drying Bed Areas, of Work Plan Addendum 020 indicate that target analyte list (TAL) metals plus cyanide were to be analyzed for at all of the SWMUs. It does not appear that samples were analyzed for cyanide, as results for this analyte could not be found in the RFI Report summary tables or in Appendix G, Analytical Data Evaluation. Please revise the RFI Report to indicate whether samples were analyzed for cyanide, and provide the results of these analyses. If cyanide was not analyzed for, revise the RFI Report to provide the justification for deviating from the Work Plan.

     Response: Upon further review, it appears that a sampling and analysis error occurred during execution of the RFI field program. The laboratory analysis for Target Analyte List (TAL) inorganics did not include cyanide.

Cyanide analysis was performed on 27 soil samples collected at SWMUs 37 and 38/Q for the SSP. Four of these samples were collected from calcium sulfate sludge contained in the drying beds. Cyanide was not identified as a COPC in soil or sludge with low concentrations detected (0.296 to 2.2 mg/kg) at levels 2 to 3 orders of magnitude below the adjusted risk-based screening levels. Based on representative results of sludge samples at these sites, cyanide is not considered a constituent of concern for these disposal areas and therefore, the lack of additional cyanide data for the RFI is not considered a significant data gap. Information on the nature of the change from work plan regarding cyanide analysis and analysis of associated uncertainties will be added to Section 3.4 of the RFI Report.

- Section 3.6.1.1, Inside Drying Bed Areas, of Work Plan Addendum 020 states that soil samples from inside SWMU 37 and SWMU 38 were to be analyzed for volatile organic compounds (VOCs) in addition to polychlorinated biphenyls (PCBs), pesticides, explosives, and metals including cyanide. Table 3-1, Field Sample Identifiers, Depths, and Analytical Methods, of the RFI Report indicates that soil samples collected from SWMU 37 were not analyzed for VOCs. Please revise the RFI Report to address this deviation from the Work Plan.

  Response: In accordance with the results of the SSP investigation and Table 4-4 from WPA 020, soil samples from inside SWMUs 37 and 38 were to be analyzed for metals, pesticides, PCBs, explosives including nitroglycerin/PETN. VOCs were not to be included in the analyses. The inclusion of VOCs in Section 3.6.1.1 was a text error.

- Table 4-4, Summary: Proposed Sample Identifiers, Depths, and Analytical Methods, of Work Plan Addendum 020 indicated that soil samples at SWMU 35 were to be analyzed for polynuclear aromatic hydrocarbons (PAHs) via SW-846 Method 8310. Table 3-1 of the RFI Report shows that soil samples at SWMU 35 were not analyzed for PAHs via SW-846 Method 8310. Please revise the RFI Report to address this deviation from the Work Plan.

  Response: Since the approval of the work plan, a method of SW-846 8270 to detect low level SVOCs (including PAHs) has been developed and is used for samples at the facility. This low-level SW-846 method has certain advantages over Method 8310 including more reliability in identifying target PAH compounds with comparable detection limits to Method 8310. Section 3.4 of the RFI Report will revised to discuss the change in analytical methods from the work plan and rationale for this change.

- Section 3.6.2.1, Monitoring Well Installation, of Work Plan Addendum 020 states that monitoring wells will be installed with a 15-foot long screen. Table 2-3, Monitoring Well and Groundwater Elevation Data, of the RFI Report shows that many of the wells have screens greater than 15 feet in length. Some wells have screens that are up to 25 feet in length (37MW1 and 38MW3). Please revise the RFI Report to address this deviation from the Work Plan. Additionally, please indicate at what depth(s) the pumps were placed during sampling.

  Response: Section 3.4 of the RFI Report will be revised include information regarding the installation of 5 to 10 foot longer well screens than proposed in the work plan. Given that the monitoring wells were installed during a period of a prolonged drought, additional screen length was installed above the water levels encountered during drilling to ensure that the top of the screen would be above seasonally high groundwater levels in the future.

  The standing water columns at the time of sampling in the RFI wells at SWMUs 35, 37, and 38/Q ranged from approximately 10 to 15 feet, with the exception of 38MW3, which had a standing water column of approximately 18 feet. Sampling pumps were placed at the mid point of the water column for low flow sampling. This addition information will be incorporated into the RFI Report.

3. The HHRA does not appear to have included all available data for SWMUs 35, 37, and SWMU 38/Area of Concern (AOC) Q in the risk evaluation. Section 2, Site Background, describes previous investigations in these three areas, including soil and groundwater sampling, dating back to the early 1990s. However, the HHRA presented in the RFI Report only evaluates soil data collected during the site screening process (SSP) investigation in 2003 and the RFI in 2007; and groundwater data collected during sampling events in February and June 2008. Please revise the HHRA to include all applicable data in the evaluation of risks in each area, and provide justification for excluding any data from sampling locations that have not been remediated.

   Response: Prior to the RFI, historical soil analytical data (1990 and 1992) were considered screening level data and excluded from the risk assessment given the age of the data, the use of non SW-846 analytical methods, the lack of available data validation reports/information, and the availability of sufficient newer validated RFI data to more appropriately characterize conditions at the site.

4. The selection of chemicals of potential concern (COPCs) in the HHRA was based on the comparison of maximum detected concentrations (MDCs) to the October 2007 EPA Region 3 Risk-Based Concentrations (RBCs) for soil and tap water. It should be noted, however, that Region 3 now relies on the Regional Screening Levels (RSLs), which are updated periodically to incorporate the most current

toxicity information and can be found online (www.epa.gov/reg3hwmd/risk/human/rb-concentration_table/index.htm). The RSLs are maintained by Oak Ridge National Laboratory under an Interagency Agreement with EPA as an update of the EPA Region 3 RBC Table, Region 6 HHMSSL Table and the Region 9 PRG Table. The RSLs may substantially differ from the RBCs since they address dermal, oral, and inhalation exposure while the RBCs only address oral exposure. In addition, the RSLs no longer support route-to-route extrapolation. It is recommended that future evaluations incorporate the RSLs, which reflect the most current toxicity data. The impacts on the overall risk conclusions by using outdated screening levels should be discussed at a minimum in the uncertainty analysis.

In addition to being used in the COPC selection process, the EPA Region 3 RBC table was also the source for toxicity data evaluated in the HHRA. As a result, the HHRA has applied outdated toxicity data for some compounds. Please revise the HHRA to incorporate the latest screening values and toxicity data provided in the RSL tables.

Response: As discussed on the August 13, 2009, Army/USEPA/VDEQ/TechLaw conference call (Discussion Point #1): Per agreements reached in partnering meetings in June 2008 and October 2008, it was approved to utilize the October 2007 RBC table for HHRAs completed or substantially complete as of that time. The revised Regional Screening Table was not released to the public until September 2008. The results of the HHRAs for SWMU 45 and RAAP 10 (SWMUs 35, 37, 38, and AOC Q) were presented at the October 2008 meeting and will therefore utilize the April 2007 RBC table. During the October 2008 partnering meeting, it was also agreed that regardless of what toxicity data is used for the HHRA for a site, the new toxicity data would be used to calculate remedial goals. For URS the new regional screening levels will be used starting with the Study Area at SWMU 13 RFI Report in compliance with previous agreements. If an updated value changed significantly so that it would impact the conclusions for the site, an analysis of the effects of this change will be conducted. A discussion of the use of the October 2007 RBC values versus the 2008 RSLs will be added to the uncertainties section of the report.

5. The HHRA makes reference to the examination of target organs in the case of non-carcinogens that exceed the target hazard index (HI) of 1. However, the RFI report does not discuss the methodology for conducting a target organ analysis, and supporting documentation is not provided to justify the removal of non-carcinogenic chemicals from further investigation based on this approach. Please supplement the discussions of HHRA methodology with a description of the target organ analysis conducted for non-carcinogens (e.g., segregation of HIs by target organs) and refer the reader to the appropriate tables in Appendix E where the target organ analysis can be located.

Response: A discussion of the methodology for conducting a target organ analysis and associated tables is included in Section 6.4, page 6-11.

6. Cancer risk estimates derived in the HHRA were compared to "EPA's target risk range for Superfund sites of 1E-06 to 1E-04" (Section 6.4, Risk Characterization, Page 6-11) resulting in the conclusion that the HHRA "did not indicate a requirement for further action for [SWMUs 35, 37, and 38/AOC Q]" (Section 6.7, HHRA Conclusions). However, the regulatory target of 1E-06 – not the risk management range – should be used as the basis for any cumulative HHRA and removal action at the site. Estimated cancer risks less than 1E-06 are considered *de minimus*, and those that fall in the risk management range (i.e., 1E-06 and 1E-04) must be evaluated further on a case-by-case basis. Risks that fall within the range are not necessarily acceptable, as it is up to the risk manager to decide whether risks within the risk management range require remedial action based on site-specific reasons. As a result, the justification for a no further action recommendation for the three areas evaluated in the RFI Report should be revised using lines of evidence other than the upper bound of the risk management range.

   Response: As requested in the October 26, 2009 email from Will Geiger (USEPA) to Jim McKenna, this comment has been disregarded.

7. The HHRA does not discuss the use of surrogate chemicals for physico-chemical data based on chemical structure and characteristics in the case of detected chemicals for which no toxicity values are available. Please address the use of surrogate chemicals to ensure that potential impacts of all COPCs are considered in the evaluation of cumulative human health risks.

   Response: The use of provisional or surrogate chemical data for COPCs at the site is discussed in Section 6.6.4.

8. The HHRA indicates that a vapor intrusion evaluation was conducted for volatile organic chemicals in groundwater using the Johnson and Ettinger Model (JEM); however, there is no discussion of the methods and assumptions used to evaluate this pathway. For example, if no occupied buildings are present at the sites, a description of the assumptions used to evaluate this pathway should be provided. To promote clarity in the document please include a discussion of how the vapor intrusion pathway was evaluated and explain the assumptions used in the model.

   Response: A discussion of the Johnson and Ettinger Model is provided in Section 6.2.3. Assumptions used to evaluate this pathway are provided in Tables E.1-4.6, E.2-4.6, and E.3-4.6 and the model results are provided in Appendix E.4.

9. The "Frequently Ask Questions" section on the Region III Ecological Risk Assessment webpage states that "Where appropriate, updated values that may be available in subsequent releases of the EPA Ecological Soil Screening Levels, and the NOAA SQuiRT values should be used in place of the values cited in the 1995

Region 3 BTAG table"
(http://www.epa.gov/reg3hscd/risk/eco/faqs/screenbench.htm). Please ensure that this statement has been accounted for when selecting plant and invertebrate Toxicity Reference Values (TRVs).

Response: As presented in the Radford SLERA framework (September 2007) per Ruth Prince, the following hierarchy will be used 1) Eco SSLs, 2) ORNL values, and 3) BTAG values in accordance with the associated table.

10. A review of the tables comparing Method Detection Limits (MDLs) of non-detect chemicals against screening values found that many chemicals were not selected as COPCs because they lacked screening values. This approach implicitly assumes that chemicals without a screening value are of no ecological concern. The *EPA 1997 Ecological Risk Assessment Guidance for Superfund* states that a contaminant should not be eliminated from the list of contaminants to be investigated only because toxicity information is lacking; instead, limited or missing toxicity information must be addressed using best professional judgment and discussed as an uncertainty. In light of this guidance, please discuss those chemicals lacking screening values in the uncertainty analysis.

    Response: The uncertainty related to the lack of toxicological data is presented in Section 7.5.4.

11. The Plant and Invertebrate/Microbial Screening tables for SWMU 35, 37, and 38/AOC Q were compared to Exposure Point Concentrations (EPCs) summary tables for each specific area. Several chemicals, such as arsenic, cadmium, iron, and selenium, lacked an EPC even though one had been calculated using ProUCL. Please revise these tables include all of the calculated EPC values.

    Response: As a refinement step, EPC HQs are only calculated for those chemicals for which the preliminary HQ (using the MDC) exceeds 1. Since the preliminary HQs for arsenic, cadmium, iron, and selenium are less than 1, a refined HQ utilizing the EPC is not calculated; therefore, the EPCs are not presented on the tables.

12. The Exposure Point Concentration Summary tables for SWMU 35, 37, and 38/AOC Q where compared against their respective SLERA Occurrence/Distribution tables. Ninety five percent (95%) UCLs were not calculated for several chemicals, such as barium, cobalt, and thallium, even though there was enough data (e.g., frequency of detection equal to 10/10). Please justify why no 95% UCLs were calculated for these chemicals.

    Response: 95% UCLs are only calculated for chemicals that have a preliminary HQ greater than 1 for at least one receptor; therefore, 95% UCLs were not calculated for barium, cobalt, and thallium.

SPECIFIC COMMENTS

13. Subsection 2.1.3 describes SWMU 35 as being situated at an elevation of approximately 1,699 to 1,701 feet above mean sea level, and being approximately 18 feet higher than the New River. Figure 2-5 describes the New River as having an elevation of 1690 feet above mean sea level. Please provide a correction to the Figure or the Subsection to rectify the differences illustrated. Please provide the elevation above mean sea level for all wells, including newly drilled wells and existing wells, used in the characterization of all SWMUs and AOCs in this RFI.

    Response: The New River has an elevation of 1680 ft above mean sea level at this location. The vertical scales of elevation of Figure 2-5 in feet mean sea level are labeled incorrectly. The correct scale for both vertical axes should start at 1660 ft and end at 1720 ft rather than the 1670 and 1730 ft shown on the figure. Figure 2-5 will be revised to show the correct scales and elevations. The text in Section 2.1.1 will be revised to reflect a 19 to 21 ft higher elevation for SWMU 35 than the New River. Elevations above mean sea level for all wells are provided in Table 2-3.

14. The New River is described as having an elevation of 1690' msl in Figure 2-5. Monitoring well 35MW2 is shown on Figure 2-6 with ground water elevation at 1685.56' msl. The ground water potentiometric surface depicted in Figure 2-5 is shown to be higher than the surface water in the New River. Explain whether these conditions are seasonal or permanent, and what they mean to the interpretation of ground water and surface water flow at these SWMU.

    Response: The vertical scales of elevation on Figure 2-5 in feet mean sea level are labeled incorrectly and therefore are inconsistent with Figure 2-6. The correct scale for both vertical axes should start at 1660 ft and end at 1720 ft rather than the 1670 ft and 1730 ft shown. Groundwater elevations in the area of SWMU 35 at 35MW1 and 35MW2 are higher than the surface water of the New River with groundwater flow toward the New River as shown on Figure 2-6. Figure 2-5 will be revised to show the correct scales and elevations.

15. If SWMU 35 ground water elevation data was collected on January 18, 2009 and shown on Figure 2-6 (dated May 2008), when was the ground water elevation data shown on Figure 2-5 (August 2008) collected? Why do neither of these figures contain the date of ground water collection? What was the elevation of the New River surface water pool at SWMU 35 on January 18, 2008?

    Response: The date on the figure in the date box is the date the figure was created not the date of the groundwater sampling event. The date (January 18, 2008) of the groundwater sampling will be added to Figures 2-5 and 2-6. Only one groundwater elevation data was collected at the site. As discussed in the response to Comments 13 and 14, the vertical scales of elevation are labeled

incorrectly on Figure 2-5 and will be revised to show the correct scales. The revised Figure 2-5 will show an river elevation of 1680 ft above mean sea level.

16. Table 6-1 provides the information regarding monitoring well locations with respect to ground water flow at each sample area. SWMU 35 has only two downgradient wells. SWMU 37 has only two downgradient wells. SWMU 38/AOC Q has no upgradient well and only two down gradient wells. Include monitoring well D-5 in the assessment of SWMU 35.

    Response: The approved work plan for the RFI for SWMU 35 included the installation and sampling of two new downgradient wells 35MW1 and 35MW2 immediately adjacent to and downgradient of SWMU 35 to appropriately evaluate potential releases to groundwater. Monitoring well D-5 was not sampled as part of the RFI at SWMU 35. Given the proximate location of 35MW1 and 35MW2 to SWMU 35 and lack of detectable site-related constituents in groundwater above adjusted risk-based screening levels, the inclusion of additional monitoring well in the RFI assessment at a location farther downgradient of the unit is not necessary.

17. Subsection 6.2.2.2 states that due to a ground water depth greater than 15 ft at SWMU 35, the construction worker is assessed only for the vapor pathway to account for potential vapors released to ambient air from groundwater beneath excavation trenches, but is not assessed for the ingestion or dermal contact pathways. Figure 2-5 is presented with both vertical and horizontal scales. Upon measuring these scales, ground water is encountered at less than 15 feet below the bottom of the calcium sulfate sludge. Figure 2-6 shows that ground water in the vicinity of SWMU 35 has a potentiometric contour of 1686.5 feet above msl which crosses the 1700 feet above msl ground surface elevation. Higher elevation potentiometric surface contours cross the same 1700 feet msl ground surface contours at fewer than 15 feet in Figure 2-6. Further, 35SB10 (Figure 2-5, Log of Boring) encountered the potentiometric surface of ground water at 16 feet below land surface, as did each boring: 35SB5, 35SB6, 35SB7 (15.5), 35SB8, and 35SB9). Furthermore, boring 35SB10 is depicted on Figure 2-5 to be terminated at the sand and gravel layer, over 2 feet below the ground water potentiometric surface as depicted on Figure 2-5. Also, please note on the boring log that 35SB10 was terminated at the sand and gravel (GM) layer.

    Response: The depth of 15 ft is the maximum depth for most utilities. Therefore, the depth of 15 ft would be from the ground surface in the area around the SWMU rather than the SWMU bottom.

18. Table 2-3 lists 35MW1 at a ground surface elevation of 1703.72 and Figure 2-5 shows the land surface elevation at 35MW1 to be over 1710 feet in elevation and ground water at about 1695', while Figure 2-6 shows ground water for 35MW1 at 1686.60'. Table 2-3 provides no sample information which coincides with the

August 2008 date on Figure 2-5. Please provide the August 2008 sampling information for all wells at SWMU 35, including D-5.

Response: Figure 2-5 will be revised. The August 2008 date on Figure 2-5 is the date the map was created rather than the date the groundwater elevations were taken. The January 18, 2008 date of the groundwater elevation data will be added to the title of the figure.

19. If the ground water data were collected on January 18, 2008 (subsection 2.1.7.1), why is the hydraulic gradient calculation dated January 29, 2008? What was the hydraulic gradient on January 18, 2008?

    Response: The table in Section 2.1.7.1 will be revised to reflect date the elevation data was collected (January 18, 2008).

20. Section 2.1.8.4 states that sample 35SL1 was tested for metals, however Table 2-4 indicates that metals were not tested.

    Response: Sample 35SL1 was sampled for TCLP metals not TAL metals. The TCLP metals results will be added to the table.

21. Figure 2-16 provides a potentiometric contour map for August 2008. However, the date box for this map states June 2008. Please clarify by including the date of data collection used in the making of this figure.

    Response: Date box is the date the map was created. This will be updated and the date of August 12, 2008 will be added to the title.

22. Figure 2-16 provides a ground water elevation for ground water well 38MW1 at 1681.50. The closest potentiometric contour line is at 1681.5, but does not go through the well point 38MW1. Please explain.

    Response: Figure 2-16 will be revised.

23. Table 2-3 presents 38MW1 at a ground surface elevation of 1709.40. Figure 2-14 shows the ground surface elevation for 38MW1 at over 1710 feet above msl. Please explain.

    Response: Figure 2-14 will be revised to show a ground surface elevation of 1709.4 ft at 38MW1.

24. Please install 3 hydrogeologically down gradient wells at SWMU 38/AOC Q. A table on page 3-3 of the draft RFI describes 3 wells as being either downgradient (2), or cross gradient (1) of SWMU 38/AOC Q. The potentiometric contour maps at Figure 2-15/2-16 shows no wells hydrogeologically downgradient of the ground surface foot print of SWMU 38/AOC Q.

Response: Further assessment of groundwater flow patterns in the SWMU 37 (November 10, 2009), SWMU 38, and AOC Q area has been conducted by obtaining one additional round of water level data from the six wells installed for the RFI (at SWMU 37/38/AOC Q) supplemented by 16 existing monitoring wells located at SWMU 9 (located between SWMU 37 and SWMU 38/AOC Q) and HWMU 7 (located adjacent to SWMU 37). This assessment confirms a north/northeasterly direction of groundwater flow across the SWMU 38/AOC Q area. Although monitoring wells are not installed directly north of this area, further assessment of groundwater at the site is not considered necessary based on the following:

- Limited calcium sulfate material is present in the drying beds at SWMU 38 (0 to 1 ft thick layer) and AOC Q (0.25 to 1 ft thick layer). This material is not a hazardous waste, does not contain hazardous constituents at levels that may pose a risk to human health or the environment, and does not represent a source area for future leaching to subsurface soil or groundwater at levels of concern;
- Risk assessment results for the site were within USEPA ranges of 1E-06 to 1E-04 for carcinogenic and 1E+00 or less for non-carcinogenic hazard when considering target organs and background; and
- Two of the three monitoring wells (38MW2and 38MW3) are installed immediately adjacent to the drying bed berms at SWMU 38 and AOC Q, and therefore, are considered appropriate locations to measure potential releases from the units due to their proximity.

25. Please install 3 hydrogeologically down gradient wells at SWMU 37. A table on page 3-3 of the draft RFI describes 3 wells as being either downgradient (2), or upgradient (1) of SWMU 37. The potentiometric contour map at Figure 2-16 shows no wells hydrogeologically downgradient of the ground surface foot print of SWMU 37.

Response: Further assessment of groundwater flow patterns in the SWMU 37 area has been conducted by obtaining one additional round of water level data from the six wells installed for the RFI (at SWMU 37/38/AOC Q) supplemented by 16 existing monitoring wells located at SWMU 9 (located between SWMU 37 and SWMU 38/AOC Q) and HWMU 7 (located adjacent to SWMU 37). This assessment shows an apparent groundwater flow divide extending across the central portion of SWMU 37 and into adjacent SWMU 9. On the western side of the divide, groundwater flows toward well 37MW3 in a northwesterly direction and on the eastern side of the divide groundwater flows toward the east-southeast. Based on this assessment, well 37MW3 is located downgradient of SWMU 37 and is appropriate for assessing releases from the unit. Well 37MW2 is also considered appropriate to evaluate potential releases from SWMU 37 due its location immediately adjacent to the drying bed. Based on the results of this additional groundwater flow assessment and results of the risk assessment, fate and transport assessment, and the characteristics of the calcium sulfate sludge, additional assessment of groundwater releases at SWMU 37 is not warranted.

26. Please provide the date of the information used in Figure 2-14, especially the potentiometric surface data. Information provided in Figure 2-16 and Figure 2-15 shows that ground water in 37MW3 is at a higher elevation that ground water in 37MW1 on two different dates. Please provide information on the ground water divide in this area.

Response: Potentiometric surface data from January 19, 2008 were used to prepare cross-section Figures 2-14 (across SWMU 38/AOC Q area) and 2-15 (across SWMU 37 area). Potentiometric representations on these figures are consistent with those shown on Figures 2-15 and 2-16. As discussed in the response to Comment 25, an additional assessment of groundwater flow has been conducted in the SWMU 37 (November 10, 2009) by obtaining one additional round of water level data from the six monitoring wells installed for the RFI (SWMU 37/38/AOC Q) supplemented by 16 existing monitoring wells located at SWMU 9 (located between SWMU 37 and SWMU 38/AOC Q) and HWMU 7 (located adjacent to SWMU 37). This assessment shows an apparent groundwater flow divide extending across the central portion of SWMU 37 and into adjacent SWMU 9. On the western side of the divide, groundwater flows toward well 37MW3 in a northwesterly direction and on the eastern side of the divide groundwater flows toward the east-southeast. The RFI Report will be revised to include a revised assessment of groundwater flow based on these measurements along with a potentiometric map showing the interpreted groundwater flow patterns.

27. Figure 2-13 illustrates the ground water elevation and potentiometric contour elevation in the vicinity of 37MW3 and 37MW1. Figure 2-15 and Figure 2-16 each indicate that ground water in 37MW3 is at a higher elevation than 37MW1. Please check these wells for an upward flow component of ground water. Please do the same for 38MW3 and 38MW1. Check to see if any of the wells screened in the bedrock are being overly influenced by the hydraulic heads in this formation, rather than formations above the bedrock. Consider installing nested wells.

Response: An additional assessment of groundwater flow (November 10, 2009), has been conducted for the SWMU 37, SWMU 38, and AOC Q using 22 monitoring wells as described in the response to Comments 25 and 26. Each of these wells is similarly constructed to monitor the uppermost zone of groundwater across the bedrock interface where hydraulic head levels are slightly above or below the bedrock surface. Hydraulic head measurements in these wells show a radial component of flow in the area of SWMU 37, SWMU 9, and HWMU 7. These flow patterns may be attributable to local conditions related to topography, drainage features, the presence of former lagoon areas (including the inactive lagoons at SWMU 9 that are partially full of water), and the site's proximity to the New River at a location of an inside bend of the river. Based on the results of this additional groundwater flow assessment, construction of the monitoring wells to

monitor the uppermost zone of groundwater, and results of the risk assessment, fate and transport assessment, and the characteristics of the calcium sulfate sludge, additional assessment of groundwater releases at SWMU 37, SWMU 38, and AOC Q is not warranted.

28. **Section 2.2.8.1, Verification Investigation – Dames and Moore 1992, Page 2-11:** This section indicates that waste characterization samples from SWMU 37, SWMU 38, and AOC Q were analyzed for VOCs, semi-volatile organic compounds (SVOCs), and toxicity characteristic leaching procedure (TCLP) metals. Table 2-6, Summary of Analytical Data for Sediment/Sludge Samples, provides the results of these analyses, but does not appear to include the TCLP metals results. Please revise the RFI Report to include the TCLP metals results of the sludge at SWMU 37, SWMU 38, and AOC Q, as these data will help classify the waste materials present in the sludge.

    Response: Historic TCLP results for SWMUs 35, 37, 38, and AOC Q will be provided. In addition, RFI TCLP results will be provided in Appendix C.6.

29. **Section 2.2.8.3, Site Screening Process Investigation – URS 2007a, Pages 2-11 to 2-12:** According to this section, a human health risk screening evaluation was conducted as part of a previous site screening process (SSP) investigation. However, although the previous screening evaluation was based on comparing MDCs with RBCs (i.e., the same approach used in the HHRA presented in the RFI Report), the two evaluations identified a few different COPCs. Specifically, the risk screening in the SSP investigation identified volatile organic compounds (VOCs), 2,4-dinitrotoluene (2,4-DNT), and metals as soil COPCs at SWMU 37; but the HHRA in the RFI Report identified metals and polychlorinated biphenyls (PCBs) as COPCs in soil. Given that the same risk screening approach was used, further explanation should be provided for the discrepancy between the COPCs identified in the two evaluations (e.g., updates in RBCs, changes in HHRA data set, etc.).

    Response: The following text will be added to Section 2.2.8.3 "Note that the COPCs identified in the SSP investigation may differ from the COPCs identified in the RFI based on updated RBC screening levels and additional soil data collected during the RFI used in the screening."

30. **Section 3.1.1, Soil Borings and Soil Sampling, Page 3-3:** The first paragraph on Page 3-3 states that "Soil samples were collected from each boring from the following depth intervals: (1) surface, (2) immediately below sludge (if present) or intermediate depth, and (3) terminal depth at specified depth." Based on the information provided in Table 3-1, Field Sample Identifiers, Depths, and Analytical Methods, the three samples per boring approach described above was not consistently applied at all of the SWMUs and AOC. One sample per boring was collected in some locations. *Work Plan Addendum 020* proposed to collect only surface soils at some locations, and this appears to be the approach that was

carried out during the RFI sampling. For clarity, please revise the statement on Page 3-3 of Section 3.1.1 to state that surface soil samples were collected from each boring, and additional subsurface soil samples (immediately below sludge or at an intermediate depth and at a terminal depth) were collected at some locations. Additionally, please describe the rationale for selection of the terminal sample depth at each of the SWMUs and AOC.

Response: In Section 3.1.1, the text will be revised as follows: "RFI soil samples were collected from each boring within the drying beds from the following depth intervals: (1) surface, (2) immediately below sludge (if present) or intermediate depth, and (3) terminal depth at specified depth. A surface soil sample was collected from the boring located outside the drying beds. As stated in WPA 020 (URS 2007), the terminal depths of the RFI borings within the drying beds of 8 ft below grade was established since additional delineation of impacted soil is not required below this depth given that concentrations of metals detected in subsurface soil samples collected from inside the drying beds are below background point estimates and the vertical organic constituent concentrations has been appropriately characterized in the SSP. In addition, the depth of the drying bed areas is 4 to 8 ft below the outside grade and therefore, samples collected from depths of 8 ft or less will provide data from the same soil strata for sample collected inside and outside of the SWMUs."

31. **Section 3.1.2, Monitoring Well Installation and Groundwater Sampling, Page 3-3:** The table included in Section 3.1.2 indicates that the groundwater sampling event at the sites was conducted in February 2008. According to Table 4-11, Summary of Detected Chemicals in Groundwater Analytical Samples at SWMU 38 and AOC Q, an additional sampling event occurred on June 24, 2008. Monitoring well 38MW3 was sampled for total and dissolved manganese on this date. The text portion of the RFI Report should describe the sampling event on June 24, 2008 and indicate why this sampling event was conducted, as it was not planned in Work Plan Addendum 020.

Response: An additional table will be added to Section 3.1.2 for the June 2008 groundwater sampling event. Section 3.1.2 text will be revised as follows: "In December 2007, monitoring wells 35MW1 and 35MW2 were installed at SWMU 35 (Figure 3-1), monitoring wells 37MW1, 37MW2, and 37MW3 were installed at SWMU 37 (Figure 3-2), and monitoring wells 38MW1, 38MW2, and 38MW3 were installed at SWMU 38/AOC Q (Figure 3-3) to evaluate potential releases to groundwater. A groundwater sampling event was completed at the sites in February 2008. Based in the results of the initial groundwater sampling event, additional confirmation groundwater sampling was conducted in June 2008 for pesticides at monitoring well 37MW2 and for manganese at 38MW3. The groundwater sampling analytical parameters are summarized below and in Table 3-1. Monitoring well construction data are summarized in Table 2-3."

32. **Section 3.4, Work Plan Field Changes, Page 3-7:** This section documents changes from the Work Plan that were initiated in the field (i.e., offsetting the locations of monitoring wells 38MW1 and 38MW2), but the RFI Report does not address any implications of these changes, or whether initial objectives of monitoring groundwater at the specified locations have been met. This section also indicates that fifteen additional stratigraphic soil borings were completed east of SWMU 38 to delineate the lateral and vertical extent of sludge in this area. The RFI Report does not appear to include any boring logs or other documentation of these borings in Appendix C nor do the additional borings appear to have specific IDs as none are shown on Figure 3-3, Sample Locations. It is also unclear whether these boring locations were surveyed. Please revise the RFI Report to describe any implications of the work plan field changes described in Section 3.4. Also, revise the RFI Report to include documentation of the fifteen additional borings that were completed east of SWMU 38, including boring logs, boring IDs, and surveyed coordinates, if available. If documentation is unavailable, indicate why this information was not collected.

Response: The monitoring well offsets did not have a significant effect on the planned assessment of groundwater conditions at SWMU 38/AOC Q because the offset locations were in the same relative position to the drying beds as originally proposed. Monitoring well 38MW2 was offset south of its planned location but at a similar position adjacent to and west of the drying bed and therefore, the location offset did not change the planned assessment of groundwater quality adjacent to the drying bed in the direction of the New River. Monitoring well 38MW1 was offset west of its planned location but remained still more than 140 feet east of the drying bed in a direction away from the New River. Section 3.4 will be revised to include this additional information.

The soil sampling and analysis table for SWMU 38 in Section 3.1.1 identifies the stratigraphic soil borings as 38SC1 through 38SC15. These borings were completed to shallow depths and therefore boring logs were not prepared. Boring information (including depth and survey coordinates) will be added to Table 2-2 and boring IDs will be added to Figure 3-3.

33. **Section 4.1.2.5, PCBs, Page 4-4:** Aroclor 1254 was detected at concentrations above its adjusted residential risk based screening criterion (R-RBC) in 8 of 22 soil samples. Based on the locations of these exceedances as shown on Figure 4-1, Extent of Human Health COPCs – Soil, it appears that the lateral extent of this contamination has not been delineated to the south and east of SWMU 35. The surface samples collected outside of the drying bed area to the south (35SB2) and east (35SB3) both reported exceedances of the R-RBC. Please revise the RFI Report to address this data gap.

Response: PCBs are not identified as a risk or hazard driver in the HHRA. Based on the small size of the site and the number of samples collected no additional characterization is necessary.

34. **Section 4.3.2.6, VOCs, Page 4-9:** Trichloroethylene (TCE) was detected in soil at SWMU 37 above its soil screening level (SSL) for migration to groundwater, based on a dilution attenuation factor (DAF) of 20. This section also notes that "groundwater sample results did not indicate leaching of TCE from soil to groundwater at detectable levels." However, it does not appear that a groundwater sample was collected at a location downgradient from the SSL exceedances at boring location 37SB2. Figure 2-15, Potentiometric Contour Map for January 2008, shows the groundwater flow direction at SWMU 37 is to the northeast. No groundwater monitoring wells are located directly northeast of SWMU 37 to monitor groundwater downgradient of the site. Please revise the RFI Report to address this data gap. Additionally, groundwater monitoring northeast of SWMU 37 may be necessary (see comment 25).

Response: As discussed in the response to Comment 25, further assessment of groundwater flow patterns in the SWMU 37 (November 10, 2009) area has been conducted by obtaining one additional round of water level data from the six wells installed for the RFI (at SWMU 37/38/AOC Q) supplemented by 16 existing monitoring wells located at SWMU 9 (located between SWMU 37 and SWMU 38/AOC Q) and HWMU 7 (located adjacent to SWMU 37). This assessment shows that well 37MW3 is appropriately positioned at a downgradient location of the drying bed in the flow path of groundwater originating from the general area of boring 37SB2 in the central portion of the drying bed. The RFI Report will be revised to include this additional information.

Based on the results of this additional groundwater flow assessment and results of the risk assessment, fate and transport assessment, and the characteristics of the calcium sulfate sludge, additional assessment of groundwater releases at SWMU 37 is not warranted.

35. **Table 4-12, Summary of Risk Screening Results for Groundwater at SWMU 38 and AOC Q:** Table 4-12 identifies the maximum detected concentrations of dissolved manganese and total manganese in groundwater as 1,050 micrograms per liter (ug/l) and 990 ug/l, respectively. Table 4-11, Summary of Detected Chemicals in Groundwater Analytical Samples at SWMU 38 and AOC Q, shows the maximum detected concentrations of dissolved and total manganese as 2,400 ug/l and 2,600 ug/l, respectively, as identified in well 38MW3 during the February 2008 sampling event. Please revise the RFI Report to address this discrepancy. The maximum detected concentrations for total and dissolved manganese as shown on Table 4-11 should be used in any evaluations of risk unless additional justification is provided.

Response: As discussed on the August 13, 2009, Army/USEPA/VDEQ/TechLaw conference call (Discussion Point #1): Betty Ann Quinn stated that she wanted to see both sets of analytical data, but that typically, only the dissolved metals concentrations needed to be carried through in

the risk assessment. She also added that, if it appeared that there was something unusual about the results, the total metals may be more representative of aquifer conditions. The detected concentrations of total and dissolved manganese do not indicate any unusual conditions at the site.

36. **Section 5.0, Contaminant Fate and Transport, Page 5-1:** This section presents a table that summarizes the COPCs identified at "the site". However, the chemicals listed are not COPCs in all three areas (i.e., SWMUs 35, 37, and 38/AOC Q). Furthermore, the difference between the chemicals listed under the column headings "Soil – Human Health" and "Soil SSL DAF20" in the table is unclear. Please revise the table to identify the specific COPCs associated with each area; and add as a footnote or incorporate into the text an explanation of the columns in the table.

    Response: The summary table in Section 5.0 will be revised.

37. **Section 5.3, Fate and Transport Summary:** Further investigation of the source of the pesticides in groundwater at SWMU 37 may be warranted.

    Response: The pesticide detections in groundwater were not considered site related since the pesticides detected in groundwater were not detected in soil at the site and the detections from the two rounds of sampling were low level and not consistently above screening levels. Detections were not above available MCLs. Thus the available data does not suggest a source exists that requires further investigation.

38. **Section 6.1.1.1, Surface Soil and Total Soil, Page 6-2:** This section indicates that soil samples collected during the SSP investigation in 2003 and for the RFI in 2007 were evaluated in the HHRA. However, as stated in the General Comments above, other previous investigations at SWMUs 35, 37, and 38/AOC Q included soil sample collection. Please revise the HHRA to include all soil data collected previously for soils that have not been removed; or provide justification for not considering these data in the HHRA. This information should be included in the data evaluation section of the HHRA which describes what data were deemed useable for risk analysis as well as data that were excluded and the reasons for excluding the data (e.g., data did not meet data quality objectives for use in HHRA, etc.).

    Response: See response to Comment #1.

39. **Section 6.1.1.2, Groundwater, Page 6-2:** This section states that groundwater data from only the February and June 2008 sampling events were evaluated in the HHRA. However, according to Section 2, Site Background, groundwater samples were also collected during other investigations, some dating back to the early 1990s. Please revise the risk assessment to include other relevant groundwater data, or provide rationale for not including them in the risk evaluation.

Furthermore, this section makes reference to the use of "dissolved metals data". Please ensure that only data from unfiltered groundwater samples are used in the HHRA.

Response: See response to Comments #1 and #35.

40. **Section 6.1.2, Identification of COPCs, Pages 6-2 to 6-4:** The COPCs summarized in tables in this section include notes that identify chemicals that were "not carried through the HHRA due to low frequency of detection". However, the definition of "low frequency of detection" is not provided, and potential deviations to this decision rule are not fully explained. For example, nitroglycerin, which was detected at SWMU 35 at a "low" frequency of detection (i.e., 1 of 10 in surface soil, and 1 of 22 in total soil samples), was retained as a COPC because the single detected concentration was above the industrial screening levels. It is not clear whether other chemicals that were removed as COPCs due to "low frequency of detection" have been compared to RBCs. Please define "low frequency of detection" and clarify this decision rule.

Furthermore, several chemicals were identified as occurring at a "low frequency of detection" and also flagged as having no screening value available. The fate of these chemicals in the HHRA is unclear. For example, dimethylphthalate at SWMU 35; methylcyclohexane, di-n-octylphthalate and dimethylphthalate at SWMU 37; and cyclohexane and methylcyclohexane at SWMU 38/AOC Q were classified as occurring at a "low frequency of detection" as well as having no screening value available. Please clarify the steps involved in removing chemicals from further evaluation as COPCs. For conservativeness, those chemicals for which no screening criteria are available should be retained and evaluated – either quantitatively with the use of surrogates or qualitatively based on their known chemical properties. Finally, low frequency is not a line of evidence that can be used to eliminate chemicals unless a spatial analysis is conducted to determine if a single detection or low frequency of detection is in an area where a release may have occurred. It should be noted that the *Risk Assessment Guidance for Superfund* (RAGS) Part A provides guidance on the use of frequency and recommends a 5 percent frequency of detection as a limit, as long as there are at least 20 samples. Thus, a frequency of 1 of 6 for methylcyclohexane, di-n-octylphthalate and dimethylphthalate at SWMU 37 is not considered low frequency since the frequency is almost 17 percent. Please address this concern.

Response: Per Ruth Prince's e-mail on 8/22/2007, if you only have 1/10 or 2/100 detections, even if that detection exceeds a screening level, the majority of your dataset does not. Risk assessors often rule out COCs by FOD (frequency of detection, usually at a cut-off of 5%), and so do not bring these chemicals through any further risk assessment. The ProUCL approach in version 4.0 essentially does the same thing, because your EPC winds up being a nondetect value, reflecting the nature of your data distribution. There would be no sense carrying that

nondetect into further risk assessment. The only caveat I would have is if the single or few detections are really high concentrations that do not appear to be fully characterized - i.e., a hotspot needing further characterization.

Of the chemical that were detected at a low frequency of detections, nitroglycerin at SWMU 35 was retained within the risk assessment due to a value greater than the industrial screening level; therefore potentially indicating a hot spot. No chemicals other than those listed in the tables were excluded from the HHRA.

41. **Section 6.2.3, Calculation of EPCs, Page 6-7:** The second paragraph in this section indicates that EPA's ProUCL 4.0 software, released in 2007, was used to calculate the 95 percent upper confidence limit on the mean (95 percent UCL) concentrations for detected chemicals. However, it should be noted that a more recent version of the ProUCL software, Version 4.00.04, was released in February 2009. Please use the latest version of ProUCL, available online at www.epa.gov/nerlesd1/tsc/software.htm, to ensure that the latest developments in UCL calculation methodology are incorporated. This comment also applies to the use of ProUCL 4.0 for distribution testing and comparison of site data to background concentrations (Section 6.4.3, Background, Page 6-15).

    Response: This report was prepared prior to the release of ProUCL Version 4.00.04; therefore, the report will not be revised.

42. **Section 6.3, Toxicity Assessment, Page 6-8:** This section states that the EPA Region 3 RBC table was the source of chronic toxicity criteria used to quantify non-carcinogenic hazards and carcinogenic risks in the HHRA. However, as indicated in the General Comments above, the use of toxicity data presented on the RBC table instead of the more recent RSL table has resulted in the use of outdated toxicity data for some compounds. Please revise the HHRA to incorporate the latest toxicity data provided in the RSL table.

    Response: See response to Comment #4.

43. **Section 6.3.1.1, Cancer Slope Factors, Page 6-9; and Section 6.3.1.2, Reference Doses and Reference Concentrations, Pages 6-9 to 6-10:** These two sections describe the derivation of toxicity criteria for carcinogens based on cancer slope factors (CSFs), and non-carcinogens based on reference doses (RfDs), and reference concentrations (RfCs). It should be noted, however, that for risk evaluations of inhalation exposure, EPA guidance recommends that unit risk factors (URFs; for carcinogens) and RfCs (for non-carcinogens) be used instead of CSFs and RfDs. Specifically, EPA's final RAGS Volume I: Human Health Evaluation Manual (Part F, Supplemental Guidance for Inhalation Risk Assessment), issued in January 2009, indicates that inhalation CSFs and RfDs should not be used to evaluate inhalation risks because studies have shown that inhalation toxicity is not a function of inhalation rate or body weight. Please revise the HHRA to incorporate this approach.

Response: This HHRA was completed prior to the release of the inhalation guidance. Per previous agreements, URS will begin to use the new guidance with the SWMU 13 RFI.

44. **Section 6.5, HHRA Summary, Pages 6-16 to 6-19:** This section summarizes the risk results for each of the three areas evaluated in the RFI, based on EPA's target risk range of 1E-06 to 1E-04. However, as indicated in the General Comments above, the regulatory target of 1E-06 – not the risk management range – should be used as the basis for cumulative HHRAs. Risks that fall within the range are not necessarily acceptable. Please revise the summary and conclusions to indicate exposure scenarios and chemicals associated with risk estimates that exceed the 1E-06 *de minimus* target.

    Response: See response to Comment #6.

45. **Section 7.1.1.1, Ecological Site Characterization, Page 7-2.** The text states that a Virginia Department of Game and Inland Fisheries survey identified two rare plant species (i.e., Midland Sedge and Shaggy False Gromwell) associated with grassland communities at RFAAP. Please specify if the plant communities at the targeted SWMUs and AOC Q have been evaluated for the presence of these two species.

    Response: The following text will be added to Section 7.1.1.1: "No threatened wildlife species or rare plant species were identified at the site."

46. **Section 7.2.1.3, Terrestrial Wildlife, Page 7-8:** The table in this section summarizes the chemicals which either have only NOAEL HQs above 1 or NOAEL and LOAEL HQs above 1 per receptor. A few errors were identified when the table was compared to Tables F.2-14 through F.2-22. For example, cadmium, chromium, and zinc are listed as only having NOAEL HQs above 1 for the meadow vole. However, Table F.2-4 shows that HXM and nitroglycerin also have NOAEL HQs above 1. Please review this table to ensure all of the appropriate chemicals are listed.

    Response: Will review and revise summary table.

47. **Section 7.2.3, Risk Management – Scientific Management Decision Point (SMDP), Italicized Conclusion. Page 7-9:** The SMDP states that "Although metal concentrations in plants were above the screening levels, vegetation at the site is lush and diverse and indicators of chemical vegetative stress were not observed with the exception of limited gravel areas." Simply stating that the area appears lush and diverse is insufficient grounds to conclude a lack of risk. For example, it is not known if the local plant community shows a response in terms of lower species diversity, reduced growth, or other more subtle responses that might be observable when compared to an unimpacted reference location. Please

discuss in the uncertainty section the limitations of the current conclusions on the lack of risk to the plant community. This additional information will help support risk management decision making.

Response: The following text will be added to Section 7.5.3: "The qualitative nature of the conclusion of lack of risk to the plant community based on the lack of indicator of chemical vegetative stress and lush vegetation present at the site creates uncertainty since it is not known that if the local plant community shows a response in terms of lower species diversity, reduced growth, or other more subtle responses that might be observable when compared to an unimpacted reference location."

48. **Section 7.4.1.3, Terrestrial Wildlife, Page 7-12:** The table in this section summarizes the chemicals which either had only NOAEL HQs above 1 or NOAEL and LOAEL HQs above 1 per receptor. One error was identified when the table was compared to the Tables F.4-14 through F.4-22. The list of chemicals for the American Robin did not include 2, 4-Dinitroluene, which had a NOAEL above 1.0. Please revise this table accordingly.

    Response: Will review and revise summary table.

49. **Section 7.5, Exposure and risk uncertainty analysis, Page 7-13 and 7-14:** This section should be expanded to address issues associated with (a) the potential for additive toxic effects of exposure by wildlife receptors to site-related chemicals, (b) the qualitative nature of the evaluation of risk to the plant community, (c) the effect on risk conclusions of high detection limits for PCBs in several soil samples from SWMU 35 (see Table F.2-3b), and (d) any concerns associated with listed plant species.

    Response: For part (a): The following text will be added to Section 7.5.6: "An HQ of less than one indicates that the contaminant alone is unlikely to cause adverse ecological effects. The potential for risk increases as the HQ increases above one. However, this result should be considered in the context of other characteristic of the exposure area. In addition, it should be noted that the calculation of chemical specific HQs does not account for multiple chemicals acting through the same exposure mechanism."

    For part (b): See Comment #47.

    For part (c): The following text will be added to Section 7.5.1: "Elevated reporting limits for chemicals, such as PAHs at SWMU 35, could result in an underestimation of risk at the site due to potentially failing to identify a COPEC.

    For part (d): See Comment #45.

50. **Table F.2-24 (Wildlife Summary) and Table F.4-24 (Wildlife Summary):** The SLERA Wildlife Summary tables for SWMU 35 and SWMU 38/AOC Q are missing from Appendices F.2 and F.4, respectively. Please review these appendices and update accordingly.

Response: Noted.

Subject FW: RAAP 10 - SWMU 37 - Additional Groundwater Sample (UNCLASSIFIED)

History: This message has been replied to.

Classification: UNCLASSIFIED
Caveats: FOUO

Will and Jim Cutler,

Per USEPA/VDEQ's request, URS installed and sampled an additional well (37MW4) at SWMU 37 (see attached figure for location). URS has received the results for the groundwater sample for the additional well. Per the agreement at the February partnering meeting, the sample was analyzed for VOCs. The only chemical detected was toluene at a concentration of 0.22 ug/L which is below the adjusted tap water screening level (230 ug/L). See the attached lab sample results. TCE, which was the chemical of concern due to an SSL exceedance, was not detected in groundwater at the site. URS proposes that we implement the remainder of the changes set forth in the original response to comments and finalize the report which recommended No Further Action for SWMUs 35, 37, 38, and AOC Q. The final report will include additional potentiometric maps (the map presented at the February partnering meeting and a map for the most recent sampling event), as well as, revised text regarding the groundwater flow in the SWMU 37, SWMU 38, and AOC A area.

Let me know if you have any questions or comments.

Also what's the status of the our RTCs for the SWMU 13 RFI Report? Don't want this to fall off the radar.

Thanks,
Jim

Subject RAAP-10 RTCs

Jim, USEPA and VDEQ have reviewed Radford's responses to our comments on the RAAP-10 draft RFI, dated July 2009. We agree with all of the responses, with the exception of Comment #34. It is not clear from the revised Draft Potentiometric Map provided at the November 18 Meeting (formerly Figure 2-15), that a groundwater sample was obtained downgradient of soil boring 37SB2, where an elevated level of TCE was detected. Depending on where the groundwater divide occurs at SWMU 37, groundwater may be flowing to the Southeast, but passing to the North of well 37MW1.

EPA and VADEQ strongly recommend that a hydrogeologically downgradient well be installed on the east side of SWMU 37, and sampled for appropriate parameters.

As stated in the RTCs, the text, the site conceptual model, and various figures including 6-1 and 6-2 should be revised to reflect the updated interpretation of groundwater flow, including a discussion of the apparent ground water divide in the vicinity of SWMU 37, SWMU 38, and AOC Q.

Please call or email me with any questions. Thanks

Subject RE: Agenda topics for 18 Nov 2009 Partnering Meeting (UNCLASSIFIED)

History: This message has been forwarded.

Classification: UNCLASSIFIED
Caveats: FOUO

Will, Jim Cutler and all,

Attaching the following for our 18 Nov 2009 meeting.

1. Two pdf files containing examples/excerpt of Statement of Basis and Site Status Update for use in issuing the RCRA CORA Permit. Note these are internal drafts and therefore are a work in progress but wanted you to see where we are with them.

2. "List of Planned and Submitted Documents" 09 Nov 2009

3. IRP "Status Update" Nov 2009

4. Draft meeting agenda, same as I sent before

5. RTCs for SWMU 45 SSP and RAAP-010 RFI reports

Please send to others in your organization who need to see this.

Thanks,
Jim

Response to Comments (November 12, 2009)
Comments on the *Draft Solid Waste Management Units 35, 37, 38, and Area of Concern Q (RAAP-10) RCRA Facility Investigation Report* for the Radford Army Ammunition Plant (RFAAP) located in Radford, Virginia, dated July 2009 (RFI Report). Received October 2, 2009.

GENERAL COMMENTS

1. The RFI Report concludes that, on the basis of the human health risk assessment (HHRA) and ecological risk assessment results, no further action is recommended for the sites. However, calcium sulfate sludge is present at the sites. Although soil and groundwater media are not currently impacted by the sludge at unacceptable levels, the constituents in the sludge itself do not appear to have been evaluated in the risk assessments. Table 2-4, Summary of Historical Analytical Data for Sediment/Soil Samples Collected at SWMU [Solid Waste Management Unit] 35, show that lead concentrations in two sludge samples collected from SWMU 35 exceeded 50,000 milligrams per kilogram (mg/kg), well above the residential and industrial action levels (400 mg/kg and 750 mg/kg, respectively). Arsenic, chromium, mercury, nickel, silver, dinitrotoluene mixture, and phenanthrene also exceeded applicable screening criteria in sludge samples 35SE1 and 35SE2, but it does not appear that these samples were considered in the evaluation of risk. Please revise the RFI to provide further justification that the calcium sulfate sludge at the sites, and specifically at SWMU 35, will not present an unacceptable level of risk to receptors. The RFI Report should clearly substantiate that an ongoing release to groundwater from the sludge itself is not possible, in consideration of the high levels of lead and other constituents detected in historical sludge samples. Also, what is the status of the remaining sludge as a waste? Are there any regulatory ramifications with leaving it in place?

   Response: Prior to the RFI, historical soil analytical data (1990 and 1992) were considered screening level data and excluded from the risk assessment given the age of the data, the use of non SW-846 analytical methods, the lack of available data validation reports/information, and the availability of sufficient newer validated RFI data to more appropriately characterize conditions at the site. It should be noted that a results transcription error occurred for the sample result 35SE2 in Table 2-4. The lead concentration for 35SE2 should be >5,000 mg/kg rather than the >50,000 mg/kg shown in the table. Table 2-4 will be revised accordingly,

   Sample results for the RFI (including SSP) did not confirm the presence of elevated lead levels in calcium sludge detected in the two samples collected from SWMU 35 in 1990. Lead samples results for 13 of 15 RFI samples of calcium sulfate sludge were below 400 mg/kg (17 to 290 mg/kg), with the remaining two sample results at 530 and 750 mg/kg, respectively. The mean concentration of lead detected in the RFI calcium sulfate samples was 198 mg/kg.

The risk assessments for each site evaluated the potential risk associated with current/future use of the sites as the drying beds are currently configured using surface soil data (SSP/RFI data from 0 to 1 ft bgs), which includes calcium sulfate sludge present in the drying beds. As discussed in Section 6.7 of the RFI Report, the results of the human health risk assessments for SWMUs 35, 37, and 38/Q did not indicate a requirement for future action for the site on the basis of human health; calculated site-related cancer risk and hazards were within USEPA target ranges for each of the receptors evaluated when considering background, target organs, and frequency of detection, and site-specific conditions.

Sections 4.1.2, 4.3.2, and 4.5.2 of the RFI Report present a detailed nature and extent assessment for each chemical of potential concern (COPC) at SWMUs 35, 37, and 38/Q including an assessment of COPC leaching to underlying soil and groundwater. As presented in these sections, evidence of appreciable leaching of COPCs from sludge to underlying subsurface soil or groundwater has not been observed at the sites. Figures 4-1, 4-2, 4-4, 4-5, 4-7, and 4-8 illustrate the vertical attenuation of concentrations from "A" level samples of sludge in the drying bed to "B" level samples of soil immediately below the sludge.

Sections 4.1.3, 4.3.3, 4.5.3, and 5.1.4 of the RFI Report present detailed soil-to-groundwater migration assessments for identified COPCs and concluded that appreciable leaching of COPCs from calcium sulfate sludge to subsurface soil or groundwater has not occurred at the site and is unlikely to occur in the future given the following:

- The results of RFI sampling indicated low concentrations of COPCs in calcium sulfate sludge, which are unlikely to represent a significant source for leaching to subsurface soil or groundwater. The neutral pH and higher organic content of the sludge will reduce the mobility and leachability of lead, chromium, and organic COPCs present in this material.
- Appreciable leaching of COPCs from sludge to underlying subsurface soil and groundwater has not been observed at the sites more than 55 years after waste management activities began and more than 25 years after waste management activities had ceased at the site;
- The limited organic COPCs detected in calcium sulfate sludge were not detected in groundwater samples collected at the sites;
- The primary inorganic COPCs detected in calcium sulfate sludge, lead and chromium, were not detected at dissolved concentrations above their adjusted risk-based screening levels.

The calcium sulfate sludge present in the drying beds is solid waste as defined in 40 CFR §261.2 but is not a listed hazardous waste or characteristic hazardous waste. Hazardous waste characteristics of the sludge were assessed by analyzing one composite sample of sludge from each drying bed for corrosivity (pH) and toxicity (full toxicity characteristic leaching procedure [TCLP] analysis).

Reactivity of the sludge was evaluated by analyzing discrete sludge samples for explosives content by SW-846 Methods 8330 and 8332; selected sludge samples were also analyzed for cyanide. Waste characterization results are presented in the attached table and summarized below:

- Sludge samples had pH levels in the range of 7.5 to 7.9 and therefore this material does not exhibit the characteristic of corrosivity as defined in 40 CFR §261.22;
- TCLP levels of sludge samples are below regulatory limits specified in 40 CRF § 261.24, and therefore this material does not exhibit the characteristic of toxicity;
- TCLP detections are limited to low levels of barium, silver, and chromium (one sample) at levels approximately three orders of magnitude below regulatory limits; and
- Explosives and cyanide are present in some of the sludge samples at low concentrations below human health risk-based screening levels and therefore this material does not exhibit the characteristic of reactivity as defined in 40 CFR §261.23.

Specific regulatory ramifications have not been identified for leaving the material in place given that the material is not a hazardous waste, does not contain hazardous constituents at levels that may pose a risk to human health or the environment, and does not represent a source area for future leaching to subsurface soil or groundwater at levels of concern.

2. There appear to be a few deviations from the work proposed in the *Final Work Plan Addendum 020 for RCRA Facility Investigation at Solid Waste Management Units 35, 37, 38, and Area of Concern Q (Work Plan Addendum 020)*, dated October 2007, that are not addressed in the RFI Report. The following deviations were noted:

    - Section 3.6.1.1, Inside Drying Bed Areas, and Section 3.6.1.2, Outside Drying Bed Areas, of Work Plan Addendum 020 indicate that target analyte list (TAL) metals plus cyanide were to be analyzed for at all of the SWMUs. It does not appear that samples were analyzed for cyanide, as results for this analyte could not be found in the RFI Report summary tables or in Appendix G, Analytical Data Evaluation. Please revise the RFI Report to indicate whether samples were analyzed for cyanide, and provide the results of these analyses. If cyanide was not analyzed for, revise the RFI Report to provide the justification for deviating from the Work Plan.

      Response: Upon further review, it appears that a sampling and analysis error occurred during execution of the RFI field program. The laboratory analysis for Target Analyte List (TAL) inorganics did not include cyanide.

Cyanide analysis was performed on 27 soil samples collected at SWMUs 37 and 38/Q for the SSP. Four of these samples were collected from calcium sulfate sludge contained in the drying beds. Cyanide was not identified as a COPC in soil or sludge with low concentrations detected (0.296 to 2.2 mg/kg) at levels 2 to 3 orders of magnitude below the adjusted risk-based screening levels. Based on representative results of sludge samples at these sites, cyanide is not considered a constituent of concern for these disposal areas and therefore, the lack of additional cyanide data for the RFI is not considered a significant data gap. Information on the nature of the change from work plan regarding cyanide analysis and analysis of associated uncertainties will be added to Section 3.4 of the RFI Report.

- Section 3.6.1.1, Inside Drying Bed Areas, of Work Plan Addendum 020 states that soil samples from inside SWMU 37 and SWMU 38 were to be analyzed for volatile organic compounds (VOCs) in addition to polychlorinated biphenyls (PCBs), pesticides, explosives, and metals including cyanide. Table 3-1, Field Sample Identifiers, Depths, and Analytical Methods, of the RFI Report indicates that soil samples collected from SWMU 37 were not analyzed for VOCs. Please revise the RFI Report to address this deviation from the Work Plan.

  Response: In accordance with the results of the SSP investigation and Table 4-4 from WPA 020, soil samples from inside SWMUs 37 and 38 were to be analyzed for metals, pesticides, PCBs, explosives including nitroglycerin/PETN. VOCs were not to be included in the analyses. The inclusion of VOCs in Section 3.6.1.1 was a text error.

- Table 4-4, Summary: Proposed Sample Identifiers, Depths, and Analytical Methods, of Work Plan Addendum 020 indicated that soil samples at SWMU 35 were to be analyzed for polynuclear aromatic hydrocarbons (PAHs) via SW-846 Method 8310. Table 3-1 of the RFI Report shows that soil samples at SWMU 35 were not analyzed for PAHs via SW-846 Method 8310. Please revise the RFI Report to address this deviation from the Work Plan.

  Response: Since the approval of the work plan, a method of SW-846 8270 to detect low level SVOCs (including PAHs) has been developed and is used for samples at the facility. This low-level SW-846 method has certain advantages over Method 8310 including more reliability in identifying target PAH compounds with comparable detection limits to Method 8310. Section 3.4 of the RFI Report will revised to discuss the change in analytical methods from the work plan and rationale for this change.

- Section 3.6.2.1, Monitoring Well Installation, of Work Plan Addendum 020 states that monitoring wells will be installed with a 15-foot long screen. Table 2-3, Monitoring Well and Groundwater Elevation Data, of the RFI Report shows that many of the wells have screens greater than 15 feet in length. Some wells have screens that are up to 25 feet in length (37MW1 and 38MW3). Please revise the RFI Report to address this deviation from the Work Plan. Additionally, please indicate at what depth(s) the pumps were placed during sampling.

  Response: Section 3.4 of the RFI Report will be revised include information regarding the installation of 5 to 10 foot longer well screens than proposed in the work plan. Given that the monitoring wells were installed during a period of a prolonged drought, additional screen length was installed above the water levels encountered during drilling to ensure that the top of the screen would be above seasonally high groundwater levels in the future.

  The standing water columns at the time of sampling in the RFI wells at SWMUs 35, 37, and 38/Q ranged from approximately 10 to 15 feet, with the exception of 38MW3, which had a standing water column of approximately 18 feet. Sampling pumps were placed at the mid point of the water column for low flow sampling. This addition information will be incorporated into the RFI Report.

3. The HHRA does not appear to have included all available data for SWMUs 35, 37, and SWMU 38/Area of Concern (AOC) Q in the risk evaluation. Section 2, Site Background, describes previous investigations in these three areas, including soil and groundwater sampling, dating back to the early 1990s. However, the HHRA presented in the RFI Report only evaluates soil data collected during the site screening process (SSP) investigation in 2003 and the RFI in 2007; and groundwater data collected during sampling events in February and June 2008. Please revise the HHRA to include all applicable data in the evaluation of risks in each area, and provide justification for excluding any data from sampling locations that have not been remediated.

   Response: Prior to the RFI, historical soil analytical data (1990 and 1992) were considered screening level data and excluded from the risk assessment given the age of the data, the use of non SW-846 analytical methods, the lack of available data validation reports/information, and the availability of sufficient newer validated RFI data to more appropriately characterize conditions at the site.

4. The selection of chemicals of potential concern (COPCs) in the HHRA was based on the comparison of maximum detected concentrations (MDCs) to the October 2007 EPA Region 3 Risk-Based Concentrations (RBCs) for soil and tap water. It should be noted, however, that Region 3 now relies on the Regional Screening Levels (RSLs), which are updated periodically to incorporate the most current

toxicity information and can be found online (www.epa.gov/reg3hwmd/risk/human/rb-concentration_table/index.htm). The RSLs are maintained by Oak Ridge National Laboratory under an Interagency Agreement with EPA as an update of the EPA Region 3 RBC Table, Region 6 HHMSSL Table and the Region 9 PRG Table. The RSLs may substantially differ from the RBCs since they address dermal, oral, and inhalation exposure while the RBCs only address oral exposure. In addition, the RSLs no longer support route-to-route extrapolation. It is recommended that future evaluations incorporate the RSLs, which reflect the most current toxicity data. The impacts on the overall risk conclusions by using outdated screening levels should be discussed at a minimum in the uncertainty analysis.

In addition to being used in the COPC selection process, the EPA Region 3 RBC table was also the source for toxicity data evaluated in the HHRA. As a result, the HHRA has applied outdated toxicity data for some compounds. Please revise the HHRA to incorporate the latest screening values and toxicity data provided in the RSL tables.

Response: As discussed on the August 13, 2009, Army/USEPA/VDEQ/TechLaw conference call (Discussion Point #1): Per agreements reached in partnering meetings in June 2008 and October 2008, it was approved to utilize the October 2007 RBC table for HHRAs completed or substantially complete as of that time. The revised Regional Screening Table was not released to the public until September 2008. The results of the HHRAs for SWMU 45 and RAAP 10 (SWMUs 35, 37, 38, and AOC Q) were presented at the October 2008 meeting and will therefore utilize the April 2007 RBC table. During the October 2008 partnering meeting, it was also agreed that regardless of what toxicity data is used for the HHRA for a site, the new toxicity data would be used to calculate remedial goals. For URS the new regional screening levels will be used starting with the Study Area at SWMU 13 RFI Report in compliance with previous agreements. If an updated value changed significantly so that it would impact the conclusions for the site, an analysis of the effects of this change will be conducted. A discussion of the use of the October 2007 RBC values versus the 2008 RSLs will be added to the uncertainties section of the report.

5. The HHRA makes reference to the examination of target organs in the case of non-carcinogens that exceed the target hazard index (HI) of 1. However, the RFI report does not discuss the methodology for conducting a target organ analysis, and supporting documentation is not provided to justify the removal of non-carcinogenic chemicals from further investigation based on this approach. Please supplement the discussions of HHRA methodology with a description of the target organ analysis conducted for non-carcinogens (e.g., segregation of HIs by target organs) and refer the reader to the appropriate tables in Appendix E where the target organ analysis can be located.

Response: A discussion of the methodology for conducting a target organ analysis and associated tables is included in Section 6.4, page 6-11.

6. Cancer risk estimates derived in the HHRA were compared to "EPA's target risk range for Superfund sites of 1E-06 to 1E-04" (Section 6.4, Risk Characterization, Page 6-11) resulting in the conclusion that the HHRA "did not indicate a requirement for further action for [SWMUs 35, 37, and 38/AOC Q]" (Section 6.7, HHRA Conclusions). However, the regulatory target of 1E-06 – not the risk management range – should be used as the basis for any cumulative HHRA and removal action at the site. Estimated cancer risks less than 1E-06 are considered *de minimus*, and those that fall in the risk management range (i.e., 1E-06 and 1E-04) must be evaluated further on a case-by-case basis. Risks that fall within the range are not necessarily acceptable, as it is up to the risk manager to decide whether risks within the risk management range require remedial action based on site-specific reasons. As a result, the justification for a no further action recommendation for the three areas evaluated in the RFI Report should be revised using lines of evidence other than the upper bound of the risk management range.

   Response: As requested in the October 26, 2009 email from Will Geiger (USEPA) to Jim McKenna, this comment has been disregarded.

7. The HHRA does not discuss the use of surrogate chemicals for physico-chemical data based on chemical structure and characteristics in the case of detected chemicals for which no toxicity values are available. Please address the use of surrogate chemicals to ensure that potential impacts of all COPCs are considered in the evaluation of cumulative human health risks.

   Response: The use of provisional or surrogate chemical data for COPCs at the site is discussed in Section 6.6.4.

8. The HHRA indicates that a vapor intrusion evaluation was conducted for volatile organic chemicals in groundwater using the Johnson and Ettinger Model (JEM); however, there is no discussion of the methods and assumptions used to evaluate this pathway. For example, if no occupied buildings are present at the sites, a description of the assumptions used to evaluate this pathway should be provided. To promote clarity in the document please include a discussion of how the vapor intrusion pathway was evaluated and explain the assumptions used in the model.

   Response: A discussion of the Johnson and Ettinger Model is provided in Section 6.2.3. Assumptions used to evaluate this pathway are provided in Tables E.1-4.6, E.2-4.6, and E.3-4.6 and the model results are provided in Appendix E.4.

9. The "Frequently Ask Questions" section on the Region III Ecological Risk Assessment webpage states that "Where appropriate, updated values that may be available in subsequent releases of the EPA Ecological Soil Screening Levels, and the NOAA SQuiRT values should be used in place of the values cited in the 1995

Region 3 BTAG table" (http://www.epa.gov/reg3hscd/risk/eco/faqs/screenbench.htm). Please ensure that this statement has been accounted for when selecting plant and invertebrate Toxicity Reference Values (TRVs).

Response: As presented in the Radford SLERA framework (September 2007) per Ruth Prince, the following hierarchy will be used 1) Eco SSLs, 2) ORNL values, and 3) BTAG values in accordance with the associated table.

10. A review of the tables comparing Method Detection Limits (MDLs) of non-detect chemicals against screening values found that many chemicals were not selected as COPCs because they lacked screening values. This approach implicitly assumes that chemicals without a screening value are of no ecological concern. The *EPA 1997 Ecological Risk Assessment Guidance for Superfund* states that a contaminant should not be eliminated from the list of contaminants to be investigated only because toxicity information is lacking; instead, limited or missing toxicity information must be addressed using best professional judgment and discussed as an uncertainty. In light of this guidance, please discuss those chemicals lacking screening values in the uncertainty analysis.

    Response: The uncertainty related to the lack of toxicological data is presented in Section 7.5.4.

11. The Plant and Invertebrate/Microbial Screening tables for SWMU 35, 37, and 38/AOC Q were compared to Exposure Point Concentrations (EPCs) summary tables for each specific area. Several chemicals, such as arsenic, cadmium, iron, and selenium, lacked an EPC even though one had been calculated using ProUCL. Please revise these tables include all of the calculated EPC values.

    Response: As a refinement step, EPC HQs are only calculated for those chemicals for which the preliminary HQ (using the MDC) exceeds 1. Since the preliminary HQs for arsenic, cadmium, iron, and selenium are less than 1, a refined HQ utilizing the EPC is not calculated; therefore, the EPCs are not presented on the tables.

12. The Exposure Point Concentration Summary tables for SWMU 35, 37, and 38/AOC Q where compared against their respective SLERA Occurrence/Distribution tables. Ninety five percent (95%) UCLs were not calculated for several chemicals, such as barium, cobalt, and thallium, even though there was enough data (e.g., frequency of detection equal to 10/10). Please justify why no 95% UCLs were calculated for these chemicals.

    Response: 95% UCLs are only calculated for chemicals that have a preliminary HQ greater than 1 for at least one receptor; therefore, 95% UCLs were not calculated for barium, cobalt, and thallium.

SPECIFIC COMMENTS

13. Subsection 2.1.3 describes SWMU 35 as being situated at an elevation of approximately 1,699 to 1,701 feet above mean sea level, and being approximately 18 feet higher than the New River. Figure 2-5 describes the New River as having an elevation of 1690 feet above mean sea level. Please provide a correction to the Figure or the Subsection to rectify the differences illustrated. Please provide the elevation above mean sea level for all wells, including newly drilled wells and existing wells, used in the characterization of all SWMUs and AOCs in this RFI.

    Response: The New River has an elevation of 1680 ft above mean sea level at this location. The vertical scales of elevation of Figure 2-5 in feet mean sea level are labeled incorrectly. The correct scale for both vertical axes should start at 1660 ft and end at 1720 ft rather than the 1670 and 1730 ft shown on the figure. Figure 2-5 will be revised to show the correct scales and elevations. The text in Section 2.1.1 will be revised to reflect a 19 to 21 ft higher elevation for SWMU 35 than the New River. Elevations above mean sea level for all wells are provided in Table 2-3.

14. The New River is described as having an elevation of 1690' msl in Figure 2-5. Monitoring well 35MW2 is shown on Figure 2-6 with ground water elevation at 1685.56' msl. The ground water potentiometric surface depicted in Figure 2-5 is shown to be higher than the surface water in the New River. Explain whether these conditions are seasonal or permanent, and what they mean to the interpretation of ground water and surface water flow at these SWMU.

    Response: The vertical scales of elevation on Figure 2-5 in feet mean sea level are labeled incorrectly and therefore are inconsistent with Figure 2-6. The correct scale for both vertical axes should start at 1660 ft and end at 1720 ft rather than the 1670 ft and 1730 ft shown. Groundwater elevations in the area of SWMU 35 at 35MW1 and 35MW2 are higher than the surface water of the New River with groundwater flow toward the New River as shown on Figure 2-6. Figure 2-5 will be revised to show the correct scales and elevations.

15. If SWMU 35 ground water elevation data was collected on January 18, 2009 and shown on Figure 2-6 (dated May 2008), when was the ground water elevation data shown on Figure 2-5 (August 2008) collected? Why do neither of these figures contain the date of ground water collection? What was the elevation of the New River surface water pool at SWMU 35 on January 18, 2008?

    Response: The date on the figure in the date box is the date the figure was created not the date of the groundwater sampling event. The date (January 18, 2008) of the groundwater sampling will be added to Figures 2-5 and 2-6. Only one groundwater elevation data was collected at the site. As discussed in the response to Comments 13 and 14, the vertical scales of elevation are labeled

incorrectly on Figure 2-5 and will be revised to show the correct scales. The revised Figure 2-5 will show an river elevation of 1680 ft above mean sea level.

16. Table 6-1 provides the information regarding monitoring well locations with respect to ground water flow at each sample area. SWMU 35 has only two downgradient wells. SWMU 37 has only two downgradient wells. SWMU 38/AOC Q has no upgradient well and only two down gradient wells. Include monitoring well D-5 in the assessment of SWMU 35.

    Response: The approved work plan for the RFI for SWMU 35 included the installation and sampling of two new downgradient wells 35MW1 and 35MW2 immediately adjacent to and downgradient of SWMU 35 to appropriately evaluate potential releases to groundwater. Monitoring well D-5 was not sampled as part of the RFI at SWMU 35. Given the proximate location of 35MW1 and 35MW2 to SWMU 35 and lack of detectable site-related constituents in groundwater above adjusted risk-based screening levels, the inclusion of additional monitoring well in the RFI assessment at a location farther downgradient of the unit is not necessary.

17. Subsection 6.2.2.2 states that due to a ground water depth greater than 15 ft at SWMU 35, the construction worker is assessed only for the vapor pathway to account for potential vapors released to ambient air from groundwater beneath excavation trenches, but is not assessed for the ingestion or dermal contact pathways. Figure 2-5 is presented with both vertical and horizontal scales. Upon measuring these scales, ground water is encountered at less than 15 feet below the bottom of the calcium sulfate sludge. Figure 2-6 shows that ground water in the vicinity of SWMU 35 has a potentiometric contour of 1686.5 feet above msl which crosses the 1700 feet above msl ground surface elevation. Higher elevation potentiometric surface contours cross the same 1700 feet msl ground surface contours at fewer than 15 feet in Figure 2-6. Further, 35SB10 (Figure 2-5, Log of Boring) encountered the potentiometric surface of ground water at 16 feet below land surface, as did each boring: 35SB5, 35SB6, 35SB7 (15.5), 35SB8, and 35SB9). Furthermore, boring 35SB10 is depicted on Figure 2-5 to be terminated at the sand and gravel layer, over 2 feet below the ground water potentiometric surface as depicted on Figure 2-5. Also, please note on the boring log that 35SB10 was terminated at the sand and gravel (GM) layer.

    Response: The depth of 15 ft is the maximum depth for most utilities. Therefore, the depth of 15 ft would be from the ground surface in the area around the SWMU rather than the SWMU bottom.

18. Table 2-3 lists 35MW1 at a ground surface elevation of 1703.72 and Figure 2-5 shows the land surface elevation at 35MW1 to be over 1710 feet in elevation and ground water at about 1695', while Figure 2-6 shows ground water for 35MW1 at 1686.60'. Table 2-3 provides no sample information which coincides with the

August 2008 date on Figure 2-5. Please provide the August 2008 sampling information for all wells at SWMU 35, including D-5.

Response: Figure 2-5 will be revised. The August 2008 date on Figure 2-5 is the date the map was created rather than the date the groundwater elevations were taken. The January 18, 2008 date of the groundwater elevation data will be added to the title of the figure.

19. If the ground water data were collected on January 18, 2008 (subsection 2.1.7.1), why is the hydraulic gradient calculation dated January 29, 2008? What was the hydraulic gradient on January 18, 2008?

    Response: The table in Section 2.1.7.1 will be revised to reflect date the elevation data was collected (January 18, 2008).

20. Section 2.1.8.4 states that sample 35SL1 was tested for metals, however Table 2-4 indicates that metals were not tested.

    Response: Sample 35SL1 was sampled for TCLP metals not TAL metals. The TCLP metals results will be added to the table.

21. Figure 2-16 provides a potentiometric contour map for August 2008. However, the date box for this map states June 2008. Please clarify by including the date of data collection used in the making of this figure.

    Response: Date box is the date the map was created. This will be updated and the date of August 12, 2008 will be added to the title.

22. Figure 2-16 provides a ground water elevation for ground water well 38MW1 at 1681.50. The closest potentiometric contour line is at 1681.5, but does not go through the well point 38MW1. Please explain.

    Response: Figure 2-16 will be revised.

23. Table 2-3 presents 38MW1 at a ground surface elevation of 1709.40. Figure 2-14 shows the ground surface elevation for 38MW1 at over 1710 feet above msl. Please explain.

    Response: Figure 2-14 will be revised to show a ground surface elevation of 1709.4 ft at 38MW1.

24. Please install 3 hydrogeologically down gradient wells at SWMU 38/AOC Q. A table on page 3-3 of the draft RFI describes 3 wells as being either downgradient (2), or cross gradient (1) of SWMU 38/AOC Q. The potentiometric contour maps at Figure 2-15/2-16 shows no wells hydrogeologically downgradient of the ground surface foot print of SWMU 38/AOC Q.

Response: Further assessment of groundwater flow patterns in the SWMU 37 (November 10, 2009), SWMU 38, and AOC Q area has been conducted by obtaining one additional round of water level data from the six wells installed for the RFI (at SWMU 37/38/AOC Q) supplemented by 16 existing monitoring wells located at SWMU 9 (located between SWMU 37 and SWMU 38/AOC Q) and HWMU 7 (located adjacent to SWMU 37). This assessment confirms a north/northeasterly direction of groundwater flow across the SWMU 38/AOC Q area. Although monitoring wells are not installed directly north of this area, further assessment of groundwater at the site is not considered necessary based on the following:

- Limited calcium sulfate material is present in the drying beds at SWMU 38 (0 to 1 ft thick layer) and AOC Q (0.25 to 1 ft thick layer). This material is not a hazardous waste, does not contain hazardous constituents at levels that may pose a risk to human health or the environment, and does not represent a source area for future leaching to subsurface soil or groundwater at levels of concern;
- Risk assessment results for the site were within USEPA ranges of 1E-06 to 1E-04 for carcinogenic and 1E+00 or less for non-carcinogenic hazard when considering target organs and background; and
- Two of the three monitoring wells (38MW2and 38MW3) are installed immediately adjacent to the drying bed berms at SWMU 38 and AOC Q, and therefore, are considered appropriate locations to measure potential releases from the units due to their proximity.

25. Please install 3 hydrogeologically down gradient wells at SWMU 37. A table on page 3-3 of the draft RFI describes 3 wells as being either downgradient (2), or upgradient (1) of SWMU 37. The potentiometric contour map at Figure 2-16 shows no wells hydrogeologically downgradient of the ground surface foot print of SWMU 37.

Response: Further assessment of groundwater flow patterns in the SWMU 37 area has been conducted by obtaining one additional round of water level data from the six wells installed for the RFI (at SWMU 37/38/AOC Q) supplemented by 16 existing monitoring wells located at SWMU 9 (located between SWMU 37 and SWMU 38/AOC Q) and HWMU 7 (located adjacent to SWMU 37). This assessment shows an apparent groundwater flow divide extending across the central portion of SWMU 37 and into adjacent SWMU 9. On the western side of the divide, groundwater flows toward well 37MW3 in a northwesterly direction and on the eastern side of the divide groundwater flows toward the east-southeast. Based on this assessment, well 37MW3 is located downgradient of SWMU 37 and is appropriate for assessing releases from the unit. Well 37MW2 is also considered appropriate to evaluate potential releases from SWMU 37 due its location immediately adjacent to the drying bed. Based on the results of this additional groundwater flow assessment and results of the risk assessment, fate and transport assessment, and the characteristics of the calcium sulfate sludge, additional assessment of groundwater releases at SWMU 37 is not warranted.

26. Please provide the date of the information used in Figure 2-14, especially the potentiometric surface data. Information provided in Figure 2-16 and Figure 2-15 shows that ground water in 37MW3 is at a higher elevation that ground water in 37MW1 on two different dates. Please provide information on the ground water divide in this area.

    Response: Potentiometric surface data from January 19, 2008 were used to prepare cross-section Figures 2-14 (across SWMU 38/AOC Q area) and 2-15 (across SWMU 37 area). Potentiometric representations on these figures are consistent with those shown on Figures 2-15 and 2-16. As discussed in the response to Comment 25, an additional assessment of groundwater flow has been conducted in the SWMU 37 (November 10, 2009) by obtaining one additional round of water level data from the six monitoring wells installed for the RFI (SWMU 37/38/AOC Q) supplemented by 16 existing monitoring wells located at SWMU 9 (located between SWMU 37 and SWMU 38/AOC Q) and HWMU 7 (located adjacent to SWMU 37). This assessment shows an apparent groundwater flow divide extending across the central portion of SWMU 37 and into adjacent SWMU 9. On the western side of the divide, groundwater flows toward well 37MW3 in a northwesterly direction and on the eastern side of the divide groundwater flows toward the east-southeast. The RFI Report will be revised to include a revised assessment of groundwater flow based on these measurements along with a potentiometric map showing the interpreted groundwater flow patterns.

27. Figure 2-13 illustrates the ground water elevation and potentiometric contour elevation in the vicinity of 37MW3 and 37MW1. Figure 2-15 and Figure 2-16 each indicate that ground water in 37MW3 is at a higher elevation than 37MW1. Please check these wells for an upward flow component of ground water. Please do the same for 38MW3 and 38MW1. Check to see if any of the wells screened in the bedrock are being overly influenced by the hydraulic heads in this formation, rather than formations above the bedrock. Consider installing nested wells.

    Response: An additional assessment of groundwater flow (November 10, 2009), has been conducted for the SWMU 37, SWMU 38, and AOC Q using 22 monitoring wells as described in the response to Comments 25 and 26. Each of these wells is similarly constructed to monitor the uppermost zone of groundwater across the bedrock interface where hydraulic head levels are slightly above or below the bedrock surface. Hydraulic head measurements in these wells show a radial component of flow in the area of SWMU 37, SWMU 9, and HWMU 7. These flow patterns may be attributable to local conditions related to topography, drainage features, the presence of former lagoon areas (including the inactive lagoons at SWMU 9 that are partially full of water), and the site's proximity to the New River at a location of an inside bend of the river. Based on the results of this additional groundwater flow assessment, construction of the monitoring wells to

monitor the uppermost zone of groundwater, and results of the risk assessment, fate and transport assessment, and the characteristics of the calcium sulfate sludge, additional assessment of groundwater releases at SWMU 37, SWMU 38, and AOC Q is not warranted.

28. **Section 2.2.8.1, Verification Investigation – Dames and Moore 1992, Page 2-11:** This section indicates that waste characterization samples from SWMU 37, SWMU 38, and AOC Q were analyzed for VOCs, semi-volatile organic compounds (SVOCs), and toxicity characteristic leaching procedure (TCLP) metals. Table 2-6, Summary of Analytical Data for Sediment/Sludge Samples, provides the results of these analyses, but does not appear to include the TCLP metals results. Please revise the RFI Report to include the TCLP metals results of the sludge at SWMU 37, SWMU 38, and AOC Q, as these data will help classify the waste materials present in the sludge.

    Response: Historic TCLP results for SWMUs 35, 37, 38, and AOC Q will be provided. In addition, RFI TCLP results will be provided in Appendix C.6.

29. **Section 2.2.8.3, Site Screening Process Investigation – URS 2007a, Pages 2-11 to 2-12:** According to this section, a human health risk screening evaluation was conducted as part of a previous site screening process (SSP) investigation. However, although the previous screening evaluation was based on comparing MDCs with RBCs (i.e., the same approach used in the HHRA presented in the RFI Report), the two evaluations identified a few different COPCs. Specifically, the risk screening in the SSP investigation identified volatile organic compounds (VOCs), 2,4-dinitrotoluene (2,4-DNT), and metals as soil COPCs at SWMU 37; but the HHRA in the RFI Report identified metals and polychlorinated biphenyls (PCBs) as COPCs in soil. Given that the same risk screening approach was used, further explanation should be provided for the discrepancy between the COPCs identified in the two evaluations (e.g., updates in RBCs, changes in HHRA data set, etc.).

    Response: The following text will be added to Section 2.2.8.3 "Note that the COPCs identified in the SSP investigation may differ from the COPCs identified in the RFI based on updated RBC screening levels and additional soil data collected during the RFI used in the screening."

30. **Section 3.1.1, Soil Borings and Soil Sampling, Page 3-3:** The first paragraph on Page 3-3 states that "Soil samples were collected from each boring from the following depth intervals: (1) surface, (2) immediately below sludge (if present) or intermediate depth, and (3) terminal depth at specified depth." Based on the information provided in Table 3-1, Field Sample Identifiers, Depths, and Analytical Methods, the three samples per boring approach described above was not consistently applied at all of the SWMUs and AOC. One sample per boring was collected in some locations. *Work Plan Addendum 020* proposed to collect only surface soils at some locations, and this appears to be the approach that was

carried out during the RFI sampling. For clarity, please revise the statement on Page 3-3 of Section 3.1.1 to state that surface soil samples were collected from each boring, and additional subsurface soil samples (immediately below sludge or at an intermediate depth and at a terminal depth) were collected at some locations. Additionally, please describe the rationale for selection of the terminal sample depth at each of the SWMUs and AOC.

Response: In Section 3.1.1, the text will be revised as follows: "RFI soil samples were collected from each boring within the drying beds from the following depth intervals: (1) surface, (2) immediately below sludge (if present) or intermediate depth, and (3) terminal depth at specified depth. A surface soil sample was collected from the boring located outside the drying beds. As stated in WPA 020 (URS 2007), the terminal depths of the RFI borings within the drying beds of 8 ft below grade was established since additional delineation of impacted soil is not required below this depth given that concentrations of metals detected in subsurface soil samples collected from inside the drying beds are below background point estimates and the vertical organic constituent concentrations has been appropriately characterized in the SSP. In addition, the depth of the drying bed areas is 4 to 8 ft below the outside grade and therefore, samples collected from depths of 8 ft or less will provide data from the same soil strata for sample collected inside and outside of the SWMUs."

31. **Section 3.1.2, Monitoring Well Installation and Groundwater Sampling, Page 3-3:** The table included in Section 3.1.2 indicates that the groundwater sampling event at the sites was conducted in February 2008. According to Table 4-11, Summary of Detected Chemicals in Groundwater Analytical Samples at SWMU 38 and AOC Q, an additional sampling event occurred on June 24, 2008. Monitoring well 38MW3 was sampled for total and dissolved manganese on this date. The text portion of the RFI Report should describe the sampling event on June 24, 2008 and indicate why this sampling event was conducted, as it was not planned in Work Plan Addendum 020.

Response: An additional table will be added to Section 3.1.2 for the June 2008 groundwater sampling event. Section 3.1.2 text will be revised as follows: "In December 2007, monitoring wells 35MW1 and 35MW2 were installed at SWMU 35 (Figure 3-1), monitoring wells 37MW1, 37MW2, and 37MW3 were installed at SWMU 37 (Figure 3-2), and monitoring wells 38MW1, 38MW2, and 38MW3 were installed at SWMU 38/AOC Q (Figure 3-3) to evaluate potential releases to groundwater. A groundwater sampling event was completed at the sites in February 2008. Based in the results of the initial groundwater sampling event, additional confirmation groundwater sampling was conducted in June 2008 for pesticides at monitoring well 37MW2 and for manganese at 38MW3. The groundwater sampling analytical parameters are summarized below and in Table 3-1. Monitoring well construction data are summarized in Table 2-3."

32. **Section 3.4, Work Plan Field Changes, Page 3-7:** This section documents changes from the Work Plan that were initiated in the field (i.e., offsetting the locations of monitoring wells 38MW1 and 38MW2), but the RFI Report does not address any implications of these changes, or whether initial objectives of monitoring groundwater at the specified locations have been met. This section also indicates that fifteen additional stratigraphic soil borings were completed east of SWMU 38 to delineate the lateral and vertical extent of sludge in this area. The RFI Report does not appear to include any boring logs or other documentation of these borings in Appendix C nor do the additional borings appear to have specific IDs as none are shown on Figure 3-3, Sample Locations. It is also unclear whether these boring locations were surveyed. Please revise the RFI Report to describe any implications of the work plan field changes described in Section 3.4. Also, revise the RFI Report to include documentation of the fifteen additional borings that were completed east of SWMU 38, including boring logs, boring IDs, and surveyed coordinates, if available. If documentation is unavailable, indicate why this information was not collected.

    Response: The monitoring well offsets did not have a significant effect on the planned assessment of groundwater conditions at SWMU 38/AOC Q because the offset locations were in the same relative position to the drying beds as originally proposed. Monitoring well 38MW2 was offset south of its planned location but at a similar position adjacent to and west of the drying bed and therefore, the location offset did not change the planned assessment of groundwater quality adjacent to the drying bed in the direction of the New River. Monitoring well 38MW1 was offset west of its planned location but remained still more than 140 feet east of the drying bed in a direction away from the New River. Section 3.4 will be revised to include this additional information.

    The soil sampling and analysis table for SWMU 38 in Section 3.1.1 identifies the stratigraphic soil borings as 38SC1 through 38SC15. These borings were completed to shallow depths and therefore boring logs were not prepared. Boring information (including depth and survey coordinates) will be added to Table 2-2 and boring IDs will be added to Figure 3-3.

33. **Section 4.1.2.5, PCBs, Page 4-4:** Aroclor 1254 was detected at concentrations above its adjusted residential risk based screening criterion (R-RBC) in 8 of 22 soil samples. Based on the locations of these exceedances as shown on Figure 4-1, Extent of Human Health COPCs – Soil, it appears that the lateral extent of this contamination has not been delineated to the south and east of SWMU 35. The surface samples collected outside of the drying bed area to the south (35SB2) and east (35SB3) both reported exceedances of the R-RBC. Please revise the RFI Report to address this data gap.

    Response: PCBs are not identified as a risk or hazard driver in the HHRA. Based on the small size of the site and the number of samples collected no additional characterization is necessary.

34. **Section 4.3.2.6, VOCs, Page 4-9:** Trichloroethylene (TCE) was detected in soil at SWMU 37 above its soil screening level (SSL) for migration to groundwater, based on a dilution attenuation factor (DAF) of 20. This section also notes that "groundwater sample results did not indicate leaching of TCE from soil to groundwater at detectable levels." However, it does not appear that a groundwater sample was collected at a location downgradient from the SSL exceedances at boring location 37SB2. Figure 2-15, Potentiometric Contour Map for January 2008, shows the groundwater flow direction at SWMU 37 is to the northeast. No groundwater monitoring wells are located directly northeast of SWMU 37 to monitor groundwater downgradient of the site. Please revise the RFI Report to address this data gap. Additionally, groundwater monitoring northeast of SWMU 37 may be necessary (see comment 25).

    Response: As discussed in the response to Comment 25, further assessment of groundwater flow patterns in the SWMU 37 (November 10, 2009) area has been conducted by obtaining one additional round of water level data from the six wells installed for the RFI (at SWMU 37/38/AOC Q) supplemented by 16 existing monitoring wells located at SWMU 9 (located between SWMU 37 and SWMU 38/AOC Q) and HWMU 7 (located adjacent to SWMU 37). This assessment shows that well 37MW3 is appropriately positioned at a downgradient location of the drying bed in the flow path of groundwater originating from the general area of boring 37SB2 in the central portion of the drying bed. The RFI Report will be revised to include this additional information.

    Based on the results of this additional groundwater flow assessment and results of the risk assessment, fate and transport assessment, and the characteristics of the calcium sulfate sludge, additional assessment of groundwater releases at SWMU 37 is not warranted.

35. **Table 4-12, Summary of Risk Screening Results for Groundwater at SWMU 38 and AOC Q:** Table 4-12 identifies the maximum detected concentrations of dissolved manganese and total manganese in groundwater as 1,050 micrograms per liter (ug/l) and 990 ug/l, respectively. Table 4-11, Summary of Detected Chemicals in Groundwater Analytical Samples at SWMU 38 and AOC Q, shows the maximum detected concentrations of dissolved and total manganese as 2,400 ug/l and 2,600 ug/l, respectively, as identified in well 38MW3 during the February 2008 sampling event. Please revise the RFI Report to address this discrepancy. The maximum detected concentrations for total and dissolved manganese as shown on Table 4-11 should be used in any evaluations of risk unless additional justification is provided.

    Response: As discussed on the August 13, 2009, Army/USEPA/VDEQ/TechLaw conference call (Discussion Point #1): Betty Ann Quinn stated that she wanted to see both sets of analytical data, but that typically, only the dissolved metals concentrations needed to be carried through in

the risk assessment. She also added that, if it appeared that there was something unusual about the results, the total metals may be more representative of aquifer conditions. The detected concentrations of total and dissolved manganese do not indicate any unusual conditions at the site.

36. **Section 5.0, Contaminant Fate and Transport, Page 5-1:** This section presents a table that summarizes the COPCs identified at "the site". However, the chemicals listed are not COPCs in all three areas (i.e., SWMUs 35, 37, and 38/AOC Q). Furthermore, the difference between the chemicals listed under the column headings "Soil – Human Health" and "Soil SSL DAF20" in the table is unclear. Please revise the table to identify the specific COPCs associated with each area; and add as a footnote or incorporate into the text an explanation of the columns in the table.

    Response: The summary table in Section 5.0 will be revised.

37. **Section 5.3, Fate and Transport Summary:** Further investigation of the source of the pesticides in groundwater at SWMU 37 may be warranted.

    Response: The pesticide detections in groundwater were not considered site related since the pesticides detected in groundwater were not detected in soil at the site and the detections from the two rounds of sampling were low level and not consistently above screening levels. Detections were not above available MCLs. Thus the available data does not suggest a source exists that requires further investigation.

38. **Section 6.1.1.1, Surface Soil and Total Soil, Page 6-2:** This section indicates that soil samples collected during the SSP investigation in 2003 and for the RFI in 2007 were evaluated in the HHRA. However, as stated in the General Comments above, other previous investigations at SWMUs 35, 37, and 38/AOC Q included soil sample collection. Please revise the HHRA to include all soil data collected previously for soils that have not been removed; or provide justification for not considering these data in the HHRA. This information should be included in the data evaluation section of the HHRA which describes what data were deemed useable for risk analysis as well as data that were excluded and the reasons for excluding the data (e.g., data did not meet data quality objectives for use in HHRA, etc.).

    Response: See response to Comment #1.

39. **Section 6.1.1.2, Groundwater, Page 6-2:** This section states that groundwater data from only the February and June 2008 sampling events were evaluated in the HHRA. However, according to Section 2, Site Background, groundwater samples were also collected during other investigations, some dating back to the early 1990s. Please revise the risk assessment to include other relevant groundwater data, or provide rationale for not including them in the risk evaluation.

Furthermore, this section makes reference to the use of "dissolved metals data". Please ensure that only data from unfiltered groundwater samples are used in the HHRA.

Response: See response to Comments #1 and #35.

40. **Section 6.1.2, Identification of COPCs, Pages 6-2 to 6-4:** The COPCs summarized in tables in this section include notes that identify chemicals that were "not carried through the HHRA due to low frequency of detection". However, the definition of "low frequency of detection" is not provided, and potential deviations to this decision rule are not fully explained. For example, nitroglycerin, which was detected at SWMU 35 at a "low" frequency of detection (i.e., 1 of 10 in surface soil, and 1 of 22 in total soil samples), was retained as a COPC because the single detected concentration was above the industrial screening levels. It is not clear whether other chemicals that were removed as COPCs due to "low frequency of detection" have been compared to RBCs. Please define "low frequency of detection" and clarify this decision rule.

    Furthermore, several chemicals were identified as occurring at a "low frequency of detection" and also flagged as having no screening value available. The fate of these chemicals in the HHRA is unclear. For example, dimethylphthalate at SWMU 35; methylcyclohexane, di-n-octylphthalate and dimethylphthalate at SWMU 37; and cyclohexane and methylcyclohexane at SWMU 38/AOC Q were classified as occurring at a "low frequency of detection" as well as having no screening value available. Please clarify the steps involved in removing chemicals from further evaluation as COPCs. For conservativeness, those chemicals for which no screening criteria are available should be retained and evaluated – either quantitatively with the use of surrogates or qualitatively based on their known chemical properties. Finally, low frequency is not a line of evidence that can be used to eliminate chemicals unless a spatial analysis is conducted to determine if a single detection or low frequency of detection is in an area where a release may have occurred. It should be noted that the *Risk Assessment Guidance for Superfund* (RAGS) Part A provides guidance on the use of frequency and recommends a 5 percent frequency of detection as a limit, as long as there are at least 20 samples. Thus, a frequency of 1 of 6 for methylcyclohexane, di-n-octylphthalate and dimethylphthalate at SWMU 37 is not considered low frequency since the frequency is almost 17 percent. Please address this concern.

    Response: Per Ruth Prince's e-mail on 8/22/2007, if you only have 1/10 or 2/100 detections, even if that detection exceeds a screening level, the majority of your dataset does not. Risk assessors often rule out COCs by FOD (frequency of detection, usually at a cut-off of 5%), and so do not bring these chemicals through any further risk assessment. The ProUCL approach in version 4.0 essentially does the same thing, because your EPC winds up being a nondetect value, reflecting the nature of your data distribution. There would be no sense carrying that

nondetect into further risk assessment. The only caveat I would have is if the single or few detections are really high concentrations that do not appear to be fully characterized - i.e., a hotspot needing further characterization.

Of the chemical that were detected at a low frequency of detections, nitroglycerin at SWMU 35 was retained within the risk assessment due to a value greater than the industrial screening level; therefore potentially indicating a hot spot. No chemicals other than those listed in the tables were excluded from the HHRA.

41. **Section 6.2.3, Calculation of EPCs, Page 6-7:** The second paragraph in this section indicates that EPA's ProUCL 4.0 software, released in 2007, was used to calculate the 95 percent upper confidence limit on the mean (95 percent UCL) concentrations for detected chemicals. However, it should be noted that a more recent version of the ProUCL software, Version 4.00.04, was released in February 2009. Please use the latest version of ProUCL, available online at www.epa.gov/nerlesd1/tsc/software.htm, to ensure that the latest developments in UCL calculation methodology are incorporated. This comment also applies to the use of ProUCL 4.0 for distribution testing and comparison of site data to background concentrations (Section 6.4.3, Background, Page 6-15).

    Response: This report was prepared prior to the release of ProUCL Version 4.00.04; therefore, the report will not be revised.

42. **Section 6.3, Toxicity Assessment, Page 6-8:** This section states that the EPA Region 3 RBC table was the source of chronic toxicity criteria used to quantify non-carcinogenic hazards and carcinogenic risks in the HHRA. However, as indicated in the General Comments above, the use of toxicity data presented on the RBC table instead of the more recent RSL table has resulted in the use of outdated toxicity data for some compounds. Please revise the HHRA to incorporate the latest toxicity data provided in the RSL table.

    Response: See response to Comment #4.

43. **Section 6.3.1.1, Cancer Slope Factors, Page 6-9; and Section 6.3.1.2, Reference Doses and Reference Concentrations, Pages 6-9 to 6-10:** These two sections describe the derivation of toxicity criteria for carcinogens based on cancer slope factors (CSFs), and non-carcinogens based on reference doses (RfDs), and reference concentrations (RfCs). It should be noted, however, that for risk evaluations of inhalation exposure, EPA guidance recommends that unit risk factors (URFs; for carcinogens) and RfCs (for non-carcinogens) be used instead of CSFs and RfDs. Specifically, EPA's final RAGS Volume I: Human Health Evaluation Manual (Part F, Supplemental Guidance for Inhalation Risk Assessment), issued in January 2009, indicates that inhalation CSFs and RfDs should not be used to evaluate inhalation risks because studies have shown that inhalation toxicity is not a function of inhalation rate or body weight. Please revise the HHRA to incorporate this approach.

Response: This HHRA was completed prior to the release of the inhalation guidance. Per previous agreements, URS will begin to use the new guidance with the SWMU 13 RFI.

44. **Section 6.5, HHRA Summary, Pages 6-16 to 6-19:** This section summarizes the risk results for each of the three areas evaluated in the RFI, based on EPA's target risk range of 1E-06 to 1E-04. However, as indicated in the General Comments above, the regulatory target of 1E-06 – not the risk management range – should be used as the basis for cumulative HHRAs. Risks that fall within the range are not necessarily acceptable. Please revise the summary and conclusions to indicate exposure scenarios and chemicals associated with risk estimates that exceed the 1E-06 *de minimus* target.

    Response: See response to Comment #6.

45. **Section 7.1.1.1, Ecological Site Characterization, Page 7-2.** The text states that a Virginia Department of Game and Inland Fisheries survey identified two rare plant species (i.e., Midland Sedge and Shaggy False Gromwell) associated with grassland communities at RFAAP. Please specify if the plant communities at the targeted SWMUs and AOC Q have been evaluated for the presence of these two species.

    Response: The following text will be added to Section 7.1.1.1: "No threatened wildlife species or rare plant species were identified at the site."

46. **Section 7.2.1.3, Terrestrial Wildlife, Page 7-8:** The table in this section summarizes the chemicals which either have only NOAEL HQs above 1 or NOAEL and LOAEL HQs above 1 per receptor. A few errors were identified when the table was compared to Tables F.2-14 through F.2-22. For example, cadmium, chromium, and zinc are listed as only having NOAEL HQs above 1 for the meadow vole. However, Table F.2-4 shows that HXM and nitroglycerin also have NOAEL HQs above 1. Please review this table to ensure all of the appropriate chemicals are listed.

    Response: Will review and revise summary table.

47. **Section 7.2.3, Risk Management – Scientific Management Decision Point (SMDP), Italicized Conclusion. Page 7-9:** The SMDP states that "Although metal concentrations in plants were above the screening levels, vegetation at the site is lush and diverse and indicators of chemical vegetative stress were not observed with the exception of limited gravel areas." Simply stating that the area appears lush and diverse is insufficient grounds to conclude a lack of risk. For example, it is not known if the local plant community shows a response in terms of lower species diversity, reduced growth, or other more subtle responses that might be observable when compared to an unimpacted reference location. Please

discuss in the uncertainty section the limitations of the current conclusions on the lack of risk to the plant community. This additional information will help support risk management decision making.

Response: The following text will be added to Section 7.5.3: "The qualitative nature of the conclusion of lack of risk to the plant community based on the lack of indicator of chemical vegetative stress and lush vegetation present at the site creates uncertainty since it is not known that if the local plant community shows a response in terms of lower species diversity, reduced growth, or other more subtle responses that might be observable when compared to an unimpacted reference location."

48. **Section 7.4.1.3, Terrestrial Wildlife, Page 7-12:** The table in this section summarizes the chemicals which either had only NOAEL HQs above 1 or NOAEL and LOAEL HQs above 1 per receptor. One error was identified when the table was compared to the Tables F.4-14 through F.4-22. The list of chemicals for the American Robin did not include 2, 4-Dinitroluene, which had a NOAEL above 1.0. Please revise this table accordingly.

    Response: Will review and revise summary table.

49. **Section 7.5, Exposure and risk uncertainty analysis, Page 7-13 and 7-14:** This section should be expanded to address issues associated with (a) the potential for additive toxic effects of exposure by wildlife receptors to site-related chemicals, (b) the qualitative nature of the evaluation of risk to the plant community, (c) the effect on risk conclusions of high detection limits for PCBs in several soil samples from SWMU 35 (see Table F.2-3b), and (d) any concerns associated with listed plant species.

    Response: For part (a): The following text will be added to Section 7.5.6: "An HQ of less than one indicates that the contaminant alone is unlikely to cause adverse ecological effects. The potential for risk increases as the HQ increases above one. However, this result should be considered in the context of other characteristic of the exposure area. In addition, it should be noted that the calculation of chemical specific HQs does not account for multiple chemicals acting through the same exposure mechanism."

    For part (b): See Comment #47.

    For part (c): The following text will be added to Section 7.5.1: "Elevated reporting limits for chemicals, such as PAHs at SWMU 35, could result in an underestimation of risk at the site due to potentially failing to identify a COPEC.

    For part (d): See Comment #45.

50. **Table F.2-24 (Wildlife Summary) and Table F.4-24 (Wildlife Summary):** The SLERA Wildlife Summary tables for SWMU 35 and SWMU 38/AOC Q are missing from Appendices F.2 and F.4, respectively. Please review these appendices and update accordingly.

    Response: Noted.

Comments SWMU 35 etc.doc

Presented below are review comments on the *Draft Solid Waste Management Units 35, 37, 38, and Area of Concern Q (RAAP-10) RCRA Facility Investigation Report* for the Radford Army Ammunition Plant (RFAAP) located in Radford, Virginia, dated July 2009 (RFI Report).

GENERAL COMMENTS

1. The RFI Report concludes that, on the basis of the human health risk assessment (HHRA) and ecological risk assessment results, no further action is recommended for the sites. However, calcium sulfate sludge is present at the sites. Although soil and groundwater media are not currently impacted by the sludge at unacceptable levels, the constituents in the sludge itself do not appear to have been evaluated in the risk assessments. Table 2-4, Summary of Historical Analytical Data for Sediment/Soil Samples Collected at SWMU [Solid Waste Management Unit] 35, show that lead concentrations in two sludge samples collected from SWMU 35 exceeded 50,000 milligrams per kilogram (mg/kg), well above the residential and industrial action levels (400 mg/kg and 750 mg/kg, respectively). Arsenic, chromium, mercury, nickel, silver, dinitrotoluene mixture, and phenanthrene also exceeded applicable screening criteria in sludge samples 35SE1 and 35SE2, but it does not appear that these samples were considered in the evaluation of risk. Please revise the RFI to provide further justification that the calcium sulfate sludge at the sites, and specifically at SWMU 35, will not present an unacceptable level of risk to receptors. The RFI Report should clearly substantiate that an ongoing release to groundwater from the sludge itself is not possible, in consideration of the high levels of lead and other constituents detected in historical sludge samples. Also, what is the status of the remaining sludge as a waste? Are there any regulatory ramifications with leaving it in place?

2. There appear to be a few deviations from the work proposed in the *Final Work Plan Addendum 020 for RCRA Facility Investigation at Solid Waste Management Units 35, 37, 38, and Area of Concern Q (Work Plan Addendum 020),* dated October 2007, that are not addressed in the RFI Report. The following deviations were noted:

    - Section 3.6.1.1, Inside Drying Bed Areas, and Section 3.6.1.2, Outside Drying Bed Areas, of Work Plan Addendum 020 indicate that target analyte list (TAL) metals plus cyanide were to be analyzed for at all of the SWMUs. It does not appear that samples were analyzed for cyanide, as results for this analyte could not be found in the RFI Report summary tables or in Appendix G, Analytical Data Evaluation. Please revise the RFI Report to indicate whether samples were analyzed for cyanide, and provide the results of these analyses. If cyanide was not analyzed for, revise the RFI Report to provide the justification for deviating from the Work Plan.

- Section 3.6.1.1, Inside Drying Bed Areas, of Work Plan Addendum 020 states that soil samples from inside SWMU 37 and SWMU 38 were to be analyzed for volatile organic compounds (VOCs) in addition to polychlorinated biphenyls (PCBs), pesticides, explosives, and metals including cyanide. Table 3-1, Field Sample Identifiers, Depths, and Analytical Methods, of the RFI Report indicates that soil samples collected from SWMU 37 were not analyzed for VOCs. Please revise the RFI Report to address this deviation from the Work Plan.

- Table 4-4, Summary: Proposed Sample Identifiers, Depths, and Analytical Methods, of Work Plan Addendum 020 indicated that soil samples at SWMU 35 were to be analyzed for polynuclear aromatic hydrocarbons (PAHs) via SW-846 Method 8310. Table 3-1 of the RFI Report shows that soil samples at SWMU 35 were not analyzed for PAHs via SW-846 Method 8310. Please revise the RFI Report to address this deviation from the Work Plan.

- Section 3.6.2.1, Monitoring Well Installation, of Work Plan Addendum 020 states that monitoring wells will be installed with a 15-foot long screen. Table 2-3, Monitoring Well and Groundwater Elevation Data, of the RFI Report shows that many of the wells have screens greater than 15 feet in length. Some wells have screens that are up to 25 feet in length (37MW1 and 38MW3). Please revise the RFI Report to address this deviation from the Work Plan. Additionally, please indicate at what depth(s) the pumps were placed during sampling.

3. The HHRA does not appear to have included all available data for SWMUs 35, 37, and SWMU 38/Area of Concern (AOC) Q in the risk evaluation. Section 2, Site Background, describes previous investigations in these three areas, including soil and groundwater sampling, dating back to the early 1990s. However, the HHRA presented in the RFI Report only evaluates soil data collected during the site screening process (SSP) investigation in 2003 and the RFI in 2007; and groundwater data collected during sampling events in February and June 2008. Please revise the HHRA to include all applicable data in the evaluation of risks in each area, and provide justification for excluding any data from sampling locations that have not been remediated.

4. The selection of chemicals of potential concern (COPCs) in the HHRA was based on the comparison of maximum detected concentrations (MDCs) to the October 2007 EPA Region 3 Risk-Based Concentrations (RBCs) for soil and tap water. It should be noted, however, that Region 3 now relies on the Regional Screening Levels (RSLs), which are updated periodically to incorporate the most current toxicity information and can be found online (www.epa.gov/reg3hwmd/risk/human/rb-concentration_table/index.htm). The RSLs are maintained by Oak Ridge National Laboratory under an Interagency Agreement with EPA as an update of the EPA Region 3 RBC Table, Region 6

HHMSSL Table and the Region 9 PRG Table. The RSLs may substantially differ from the RBCs since they address dermal, oral, and inhalation exposure while the RBCs only address oral exposure. In addition, the RSLs no longer support route-to-route extrapolation. It is recommended that future evaluations incorporate the RSLs, which reflect the most current toxicity data. The impacts on the overall risk conclusions by using outdated screening levels should be discussed at a minimum in the uncertainty analysis.

In addition to being used in the COPC selection process, the EPA Region 3 RBC table was also the source for toxicity data evaluated in the HHRA. As a result, the HHRA has applied outdated toxicity data for some compounds. Please revise the HHRA to incorporate the latest screening values and toxicity data provided in the RSL tables.

5. The HHRA makes reference to the examination of target organs in the case of non-carcinogens that exceed the target hazard index (HI) of 1. However, the RFI report does not discuss the methodology for conducting a target organ analysis, and supporting documentation is not provided to justify the removal of non-carcinogenic chemicals from further investigation based on this approach. Please supplement the discussions of HHRA methodology with a description of the target organ analysis conducted for non-carcinogens (e.g., segregation of HIs by target organs) and refer the reader to the appropriate tables in Appendix E where the target organ analysis can be located.

6. Cancer risk estimates derived in the HHRA were compared to "EPA's target risk range for Superfund sites of 1E-06 to 1E-04" (Section 6.4, Risk Characterization, Page 6-11) resulting in the conclusion that the HHRA "did not indicate a requirement for further action for [SWMUs 35, 37, and 38/AOC Q]" (Section 6.7, HHRA Conclusions). However, the regulatory target of 1E-06 – not the risk management range – should be used as the basis for any cumulative HHRA and removal action at the site. Estimated cancer risks less than 1E-06 are considered *de minimus*, and those that fall in the risk management range (i.e., 1E-06 and 1E-04) must be evaluated further on a case-by-case basis. Risks that fall within the range are not necessarily acceptable, as it is up to the risk manager to decide whether risks within the risk management range require remedial action based on site-specific reasons. As a result, the justification for a no further action recommendation for the three areas evaluated in the RFI Report should be revised using lines of evidence other than the upper bound of the risk management range.

7. The HHRA does not discuss the use of surrogate chemicals for physico-chemical data based on chemical structure and characteristics in the case of detected chemicals for which no toxicity values are available. Please address the use of surrogate chemicals to ensure that potential impacts of all COPCs are considered in the evaluation of cumulative human health risks.

8. The HHRA indicates that a vapor intrusion evaluation was conducted for volatile organic chemicals in groundwater using the Johnson and Ettinger Model (JEM);

however, there is no discussion of the methods and assumptions used to evaluate this pathway. For example, if no occupied buildings are present at the sites, a description of the assumptions used to evaluate this pathway should be provided. To promote clarity in the document please include a discussion of how the vapor intrusion pathway was evaluated and explain the assumptions used in the model.

9. The "Frequently Ask Questions" section on the Region III Ecological Risk Assessment webpage states that "Where appropriate, updated values that may be available in subsequent releases of the EPA Ecological Soil Screening Levels, and the NOAA SQuiRT values should be used in place of the values cited in the 1995 Region 3 BTAG table" (http://www.epa.gov/reg3hscd/risk/eco/faqs/screenbench.htm). Please ensure that this statement has been accounted for when selecting plant and invertebrate Toxicity Reference Values (TRVs).

10. A review of the tables comparing Method Detection Limits (MDLs) of non-detect chemicals against screening values found that many chemicals were not selected as COPCs because they lacked screening values. This approach implicitly assumes that chemicals without a screening value are of no ecological concern. The *EPA 1997 Ecological Risk Assessment Guidance for Superfund* states that a contaminant should not be eliminated from the list of contaminants to be investigated only because toxicity information is lacking; instead, limited or missing toxicity information must be addressed using best professional judgment and discussed as an uncertainty. In light of this guidance, please discuss those chemicals lacking screening values in the uncertainty analysis.

11. The Plant and Invertebrate/Microbial Screening tables for SWMU 35, 37, and 38/AOC Q were compared to Exposure Point Concentrations (EPCs) summary tables for each specific area. Several chemicals, such as arsenic, cadmium, iron, and selenium, lacked an EPC even though one had been calculated using ProUCL. Please revise these tables include all of the calculated EPC values.

12. The Exposure Point Concentration Summary tables for SWMU 35, 37, and 38/AOC Q where compared against their respective SLERA Occurrence/Distribution tables. Ninety five percent (95%) UCLs were not calculated for several chemicals, such as barium, cobalt, and thallium, even though there was enough data (e.g., frequency of detection equal to 10/10). Please justify why no 95% UCLs were calculated for these chemicals.

SPECIFIC COMMENTS

13. Subsection 2.1.3 describes SWMU 35 as being situated at an elevation of approximately 1,699 to 1,701 feet above mean sea level, and being approximately 18 feet higher than the New River. Figure 2-5 describes the New River as having an elevation of 1690 feet above mean sea level. Please provide a correction to the Figure or the Subsection to rectify the differences illustrated. Please provide the

elevation above mean sea level for all wells, including newly drilled wells and existing wells, used in the characterization of all SWMUs and AOCs in this RFI.

14. The New River is described as having an elevation of 1690' msl in Figure 2-5. Monitoring well 35MW2 is shown on Figure 2-6 with ground water elevation at 1685.56' msl. The ground water potentiometric surface depicted in Figure 2-5 is shown to be higher than the surface water in the New River. Explain whether these conditions are seasonal or permanent, and what they mean to the interpretation of ground water and surface water flow at these SWMU.

15. If SWMU 35 ground water elevation data was collected on January 18, 2009 and shown on Figure 2-6 (dated May 2008), when was the ground water elevation data shown on Figure 2-5 (August 2008) collected? Why do neither of these figures contain the date of ground water collection? What was the elevation of the New River surface water pool at SWMU 35 on January 18, 2008?

16. Table 6-1 provides the information regarding monitoring well locations with respect to ground water flow at each sample area. SWMU 35 has only two downgradient wells. SWMU 37 has only two downgradient wells. SWMU 38/AOC Q has no upgradient well and only two down gradient wells. Include monitoring well D-5 in the assessment of SWMU 35.

17. Subsection 6.2.2.2 states that due to a ground water depth greater than 15 ft at SWMU 35, the construction worker is assessed only for the vapor pathway to account for potential vapors released to ambient air from groundwater beneath excavation trenches, but is not assessed for the ingestion or dermal contact pathways. Figure 2-5 is presented with both vertical and horizontal scales. Upon measuring these scales, ground water is encountered at less than 15 feet below the bottom of the calcium sulfate sludge. Figure 2-6 shows that ground water in the vicinity of SWMU 35 has a potentiometric contour of 1686.5 feet above msl which crosses the 1700 feet above msl ground surface elevation. Higher elevation potentiometric surface contours cross the same 1700 feet msl ground surface contours at fewer than 15 feet in Figure 2-6. Further, 35SB10 (Figure 2-5, Log of Boring) encountered the potentiometric surface of ground water at 16 feet below land surface, as did each boring: 35SB5, 35SB6, 35SB7 (15.5), 35SB8, and 35SB9). Furthermore, boring 35SB10 is depicted on Figure 2-5 to be terminated at the sand and gravel layer, over 2 feet below the ground water potentiometric surface as depicted on Figure 2-5. Also, please note on the boring log that 35SB10 was terminated at the sand and gravel (GM) layer.

18. Table 2-3 lists 35MW1 at a ground surface elevation of 1703.72 and Figure 2-5 shows the land surface elevation at 35MW1 to be over 1710 feet in elevation and ground water at about 1695', while Figure 2-6 shows ground water for 35MW1 at 1686.60'. Table 2-3 provides no sample information which coincides with the August 2008 date on Figure 2-5. Please provide the August 2008 sampling information for all wells at SWMU 35, including D-5.

19. If the ground water data were collected on January 18, 2008 (subsection 2.1.7.1), why is the hydraulic gradient calculation dated January 29, 2008? What was the hydraulic gradient on January 18, 2008?

20. Section 2.1.8.4 states that sample 35SL1 was tested for metals, however Table 2-4 indicates that metals were not tested.

21. Figure 2-16 provides a potentiometric contour map for August 2008. However, the date box for this map states June 2008. Please clarify by including the date of data collection used in the making of this figure.

22. Figure 2-16 provides a ground water elevation for ground water well 38MW1 at 1681.50. The closest potentiometric contour line is at 1681.5, but does not go through the well point 38MW1. Please explain.

23. Table 2-3 presents 38MW1 at a ground surface elevation of 1709.40. Figure 2-14 shows the ground surface elevation for 38MW1 at over 1710 feet above msl. Please explain.

24. Please install 3 hydrogeologically down gradient wells at SWMU 38/AOC Q. A table on page 3-3 of the draft RFI describes 3 wells as being either downgradient (2), or cross gradient (1) of SWMU 38/AOC Q. The potentiometric contour maps at Figure 2-15/2-16 shows no wells hydrogeologically downgradient of the ground surface foot print of SWMU 38/AOC Q.

25. Please install 3 hydrogeologically down gradient wells at SWMU 37. A table on page 3-3 of the draft RFI describes 3 wells as being either downgradient (2), or upgradient (1) of SWMU 37. The potentiometric contour map at Figure 2-16 shows no wells hydrogeologically downgradient of the ground surface foot print of SWMU 37.

26. Please provide the date of the information used in Figure 2-14, especially the potentiometric surface data. Information provided in Figure 2-16 and Figure 2-15 shows that ground water in 37MW3 is at a higher elevation that ground water in 37MW1 on two different dates. Please provide information on the ground water divide in this area.

27. Figure 2-13 illustrates the ground water elevation and potentiometric contour elevation in the vicinity of 37MW3 and 37MW1. Figure 2-15 and Figure 2-16 each indicate that ground water in 37MW3 is at a higher elevation than 37MW1. Please check these wells for an upward flow component of ground water. Please do the same for 38MW3 and 38MW1. Check to see if any of the wells screened in the bedrock are being overly influenced by the hydraulic heads in this formation, rather than formations above the bedrock. Consider installing nested wells.

28. **Section 2.2.8.1, Verification Investigation – Dames and Moore 1992, Page 2-11:** This section indicates that waste characterization samples from SWMU 37, SWMU 38, and AOC Q were analyzed for VOCs, semi-volatile organic compounds (SVOCs), and toxicity characteristic leaching procedure (TCLP) metals. Table 2-6, Summary of Analytical Data for Sediment/Sludge Samples, provides the results of these analyses, but does not appear to include the TCLP metals results. Please revise the RFI Report to include the TCLP metals results of the sludge at SWMU 37, SWMU 38, and AOC Q, as these data will help classify the waste materials present in the sludge.

29. **Section 2.2.8.3, Site Screening Process Investigation – URS 2007a, Pages 2-11 to 2-12:** According to this section, a human health risk screening evaluation was conducted as part of a previous site screening process (SSP) investigation. However, although the previous screening evaluation was based on comparing MDCs with RBCs (i.e., the same approach used in the HHRA presented in the RFI Report), the two evaluations identified a few different COPCs. Specifically, the risk screening in the SSP investigation identified volatile organic compounds (VOCs), 2,4-dinitrotoluene (2,4-DNT), and metals as soil COPCs at SWMU 37; but the HHRA in the RFI Report identified metals and polychlorinated biphenyls (PCBs) as COPCs in soil. Given that the same risk screening approach was used, further explanation should be provided for the discrepancy between the COPCs identified in the two evaluations (e.g., updates in RBCs, changes in HHRA data set, etc.).

30. **Section 3.1.1, Soil Borings and Soil Sampling, Page 3-3:** The first paragraph on Page 3-3 states that "Soil samples were collected from each boring from the following depth intervals: (1) surface, (2) immediately below sludge (if present) or intermediate depth, and (3) terminal depth at specified depth." Based on the information provided in Table 3-1, Field Sample Identifiers, Depths, and Analytical Methods, the three samples per boring approach described above was not consistently applied at all of the SWMUs and AOC. One sample per boring was collected in some locations. *Work Plan Addendum 020* proposed to collect only surface soils at some locations, and this appears to be the approach that was carried out during the RFI sampling. For clarity, please revise the statement on Page 3-3 of Section 3.1.1 to state that surface soil samples were collected from each boring, and additional subsurface soil samples (immediately below sludge or at an intermediate depth and at a terminal depth) were collected at some locations. Additionally, please describe the rationale for selection of the terminal sample depth at each of the SWMUs and AOC.

31. **Section 3.1.2, Monitoring Well Installation and Groundwater Sampling, Page 3-3:** The table included in Section 3.1.2 indicates that the groundwater sampling event at the sites was conducted in February 2008. According to Table 4-11, Summary of Detected Chemicals in Groundwater Analytical Samples at SWMU 38 and AOC Q, an additional sampling event occurred on June 24, 2008.

Monitoring well 38MW3 was sampled for total and dissolved manganese on this date. The text portion of the RFI Report should describe the sampling event on June 24, 2008 and indicate why this sampling event was conducted, as it was not planned in Work Plan Addendum 020.

32. **Section 3.4, Work Plan Field Changes, Page 3-7:** This section documents changes from the Work Plan that were initiated in the field (i.e., offsetting the locations of monitoring wells 38MW1 and 38MW2), but the RFI Report does not address any implications of these changes, or whether initial objectives of monitoring groundwater at the specified locations have been met. This section also indicates that fifteen additional stratigraphic soil borings were completed east of SWMU 38 to delineate the lateral and vertical extent of sludge in this area. The RFI Report does not appear to include any boring logs or other documentation of these borings in Appendix C nor do the additional borings appear to have specific IDs as none are shown on Figure 3-3, Sample Locations. It is also unclear whether these boring locations were surveyed. Please revise the RFI Report to describe any implications of the work plan field changes described in Section 3.4. Also, revise the RFI Report to include documentation of the fifteen additional borings that were completed east of SWMU 38, including boring logs, boring IDs, and surveyed coordinates, if available. If documentation is unavailable, indicate why this information was not collected.

33. **Section 4.1.2.5, PCBs, Page 4-4:** Aroclor 1254 was detected at concentrations above its adjusted residential risk based screening criterion (R-RBC) in 8 of 22 soil samples. Based on the locations of these exceedances as shown on Figure 4-1, Extent of Human Health COPCs – Soil, it appears that the lateral extent of this contamination has not been delineated to the south and east of SWMU 35. The surface samples collected outside of the drying bed area to the south (35SB2) and east (35SB3) both reported exceedances of the R-RBC. Please revise the RFI Report to address this data gap.

34. **Section 4.3.2.6, VOCs, Page 4-9:** Trichloroethylene (TCE) was detected in soil at SWMU 37 above its soil screening level (SSL) for migration to groundwater, based on a dilution attenuation factor (DAF) of 20. This section also notes that "groundwater sample results did not indicate leaching of TCE from soil to groundwater at detectable levels." However, it does not appear that a groundwater sample was collected at a location downgradient from the SSL exceedances at boring location 37SB2. Figure 2-15, Potentiometric Contour Map for January 2008, shows the groundwater flow direction at SWMU 37 is to the northeast. No groundwater monitoring wells are located directly northeast of SWMU 37 to monitor groundwater downgradient of the site. Please revise the RFI Report to address this data gap. Additionally, groundwater monitoring northeast of SWMU 37 may be necessary (see comment 25).

35. **Table 4-12, Summary of Risk Screening Results for Groundwater at SWMU 38 and AOC Q:** Table 4-12 identifies the maximum detected concentrations of

dissolved manganese and total manganese in groundwater as 1,050 micrograms per liter (ug/l) and 990 ug/l, respectively. Table 4-11, Summary of Detected Chemicals in Groundwater Analytical Samples at SWMU 38 and AOC Q, shows the maximum detected concentrations of dissolved and total manganese as 2,400 ug/l and 2,600 ug/l, respectively, as identified in well 38MW3 during the February 2008 sampling event. Please revise the RFI Report to address this discrepancy. The maximum detected concentrations for total and dissolved manganese as shown on Table 4-11 should be used in any evaluations of risk unless additional justification is provided.

36. **Section 5.0, Contaminant Fate and Transport, Page 5-1:** This section presents a table that summarizes the COPCs identified at "the site". However, the chemicals listed are not COPCs in all three areas (i.e., SWMUs 35, 37, and 38/AOC Q). Furthermore, the difference between the chemicals listed under the column headings "Soil – Human Health" and "Soil SSL DAF20" in the table is unclear. Please revise the table to identify the specific COPCs associated with each area; and add as a footnote or incorporate into the text an explanation of the columns in the table.

37. **Section 5.3, Fate and Transport Summary:** Further investigation of the source of the pesticides in groundwater at SWMU 37 may be warranted.

38. **Section 6.1.1.1, Surface Soil and Total Soil, Page 6-2:** This section indicates that soil samples collected during the SSP investigation in 2003 and for the RFI in 2007 were evaluated in the HHRA. However, as stated in the General Comments above, other previous investigations at SWMUs 35, 37, and 38/AOC Q included soil sample collection. Please revise the HHRA to include all soil data collected previously for soils that have not been removed; or provide justification for not considering these data in the HHRA. This information should be included in the data evaluation section of the HHRA which describes what data were deemed useable for risk analysis as well as data that were excluded and the reasons for excluding the data (e.g., data did not meet data quality objectives for use in HHRA, etc.).

39. **Section 6.1.1.2, Groundwater, Page 6-2:** This section states that groundwater data from only the February and June 2008 sampling events were evaluated in the HHRA. However, according to Section 2, Site Background, groundwater samples were also collected during other investigations, some dating back to the early 1990s. Please revise the risk assessment to include other relevant groundwater data, or provide rationale for not including them in the risk evaluation. Furthermore, this section makes reference to the use of "dissolved metals data". Please ensure that only data from unfiltered groundwater samples are used in the HHRA.

40. **Section 6.1.2, Identification of COPCs, Pages 6-2 to 6-4:** The COPCs summarized in tables in this section include notes that identify chemicals that

were "not carried through the HHRA due to low frequency of detection". However, the definition of "low frequency of detection" is not provided, and potential deviations to this decision rule are not fully explained. For example, nitroglycerin, which was detected at SWMU 35 at a "low" frequency of detection (i.e., 1 of 10 in surface soil, and 1 of 22 in total soil samples), was retained as a COPC because the single detected concentration was above the industrial screening levels. It is not clear whether other chemicals that were removed as COPCs due to "low frequency of detection" have been compared to RBCs. Please define "low frequency of detection" and clarify this decision rule.

Furthermore, several chemicals were identified as occurring at a "low frequency of detection" and also flagged as having no screening value available. The fate of these chemicals in the HHRA is unclear. For example, dimethylphthalate at SWMU 35; methylcyclohexane, di-n-octylphthalate and dimethylphthalate at SWMU 37; and cyclohexane and methylcyclohexane at SWMU 38/AOC Q were classified as occurring at a "low frequency of detection" as well as having no screening value available. Please clarify the steps involved in removing chemicals from further evaluation as COPCs. For conservativeness, those chemicals for which no screening criteria are available should be retained and evaluated – either quantitatively with the use of surrogates or qualitatively based on their known chemical properties. Finally, low frequency is not a line of evidence that can be used to eliminate chemicals unless a spatial analysis is conducted to determine if a single detection or low frequency of detection is in an area where a release may have occurred. It should be noted that the *Risk Assessment Guidance for Superfund* (RAGS) Part A provides guidance on the use of frequency and recommends a 5 percent frequency of detection as a limit, as long as there are at least 20 samples. Thus, a frequency of 1 of 6 for methylcyclohexane, di-n-octylphthalate and dimethylphthalate at SWMU 37 is not considered low frequency since the frequency is almost 17 percent. Please address this concern.

41. **Section 6.2.3, Calculation of EPCs, Page 6-7:** The second paragraph in this section indicates that EPA's ProUCL 4.0 software, released in 2007, was used to calculate the 95 percent upper confidence limit on the mean (95 percent UCL) concentrations for detected chemicals. However, it should be noted that a more recent version of the ProUCL software, Version 4.00.04, was released in February 2009. Please use the latest version of ProUCL, available online at www.epa.gov/nerlesd1/tsc/software.htm, to ensure that the latest developments in UCL calculation methodology are incorporated. This comment also applies to the use of ProUCL 4.0 for distribution testing and comparison of site data to background concentrations (Section 6.4.3, Background, Page 6-15).

42. **Section 6.3, Toxicity Assessment, Page 6-8:** This section states that the EPA Region 3 RBC table was the source of chronic toxicity criteria used to quantify non-carcinogenic hazards and carcinogenic risks in the HHRA. However, as indicated in the General Comments above, the use of toxicity data presented on the RBC table instead of the more recent RSL table has resulted in the use of

outdated toxicity data for some compounds. Please revise the HHRA to incorporate the latest toxicity data provided in the RSL table.

43. **Section 6.3.1.1, Cancer Slope Factors, Page 6-9; and Section 6.3.1.2, Reference Doses and Reference Concentrations, Pages 6-9 to 6-10:** These two sections describe the derivation of toxicity criteria for carcinogens based on cancer slope factors (CSFs), and non-carcinogens based on reference doses (RfDs), and reference concentrations (RfCs). It should be noted, however, that for risk evaluations of inhalation exposure, EPA guidance recommends that unit risk factors (URFs; for carcinogens) and RfCs (for non-carcinogens) be used instead of CSFs and RfDs. Specifically, EPA's final RAGS Volume I: Human Health Evaluation Manual (Part F, Supplemental Guidance for Inhalation Risk Assessment), issued in January 2009, indicates that inhalation CSFs and RfDs should not be used to evaluate inhalation risks because studies have shown that inhalation toxicity is not a function of inhalation rate or body weight. Please revise the HHRA to incorporate this approach.

44. **Section 6.5, HHRA Summary, Pages 6-16 to 6-19:** This section summarizes the risk results for each of the three areas evaluated in the RFI, based on EPA's target risk range of 1E-06 to 1E-04. However, as indicated in the General Comments above, the regulatory target of 1E-06 – not the risk management range – should be used as the basis for cumulative HHRAs. Risks that fall within the range are not necessarily acceptable. Please revise the summary and conclusions to indicate exposure scenarios and chemicals associated with risk estimates that exceed the 1E-06 *de minimus* target.

45. **Section 7.1.1.1, Ecological Site Characterization, Page 7-2.** The text states that a Virginia Department of Game and Inland Fisheries survey identified two rare plant species (i.e., Midland Sedge and Shaggy False Gromwell) associated with grassland communities at RFAAP. Please specify if the plant communities at the targeted SWMUs and AOC Q have been evaluated for the presence of these two species.

46. **Section 7.2.1.3, Terrestrial Wildlife, Page 7-8:** The table in this section summarizes the chemicals which either have only NOAEL HQs above 1 or NOAEL and LOAEL HQs above 1 per receptor. A few errors were identified when the table was compared to Tables F.2-14 through F.2-22. For example, cadmium, chromium, and zinc are listed as only having NOAEL HQs above 1 for the meadow vole. However, Table F.2-4 shows that HXM and nitroglycerin also have NOAEL HQs above 1. Please review this table to ensure all of the appropriate chemicals are listed.

47. **Section 7.2.3, Risk Management – Scientific Management Decision Point (SMDP), Italicized Conclusion. Page 7-9:** The SMDP states that "Although metal concentrations in plants were above the screening levels, vegetation at the

site is lush and diverse and indicators of chemical vegetative stress were not observed with the exception of limited gravel areas." Simply stating that the area appears lush and diverse is insufficient grounds to conclude a lack of risk. For example, it is not known if the local plant community shows a response in terms of lower species diversity, reduced growth, or other more subtle responses that might be observable when compared to an unimpacted reference location. Please discuss in the uncertainty section the limitations of the current conclusions on the lack of risk to the plant community. This additional information will help support risk management decision making.

48. **Section 7.4.1.3, Terrestrial Wildlife, Page 7-12:** The table in this section summarizes the chemicals which either had only NOAEL HQs above 1 or NOAEL and LOAEL HQs above 1 per receptor. One error was identified when the table was compared to the Tables F.4-14 through F.4-22. The list of chemicals for the American Robin did not include 2, 4-Dinitroluene, which had a NOAEL above 1.0. Please revise this table accordingly.

49. **Section 7.5, Exposure and risk uncertainty analysis, Page 7-13 and 7-14:** This section should be expanded to address issues associated with (a) the potential for additive toxic effects of exposure by wildlife receptors to site-related chemicals, (b) the qualitative nature of the evaluation of risk to the plant community, (c) the effect on risk conclusions of high detection limits for PCBs in several soil samples from SWMU 35 (see Table F.2-3b), and (d) any concerns associated with listed plant species.

50. **Table F.2-24 (Wildlife Summary) and Table F.4-24 (Wildlife Summary):** The SLERA Wildlife Summary tables for SWMU 35 and SWMU 38/AOC Q are missing from Appendices F.2 and F.4, respectively. Please review these appendices and update accordingly.

MEMORANDUM FOR Office of Environmental Quality, Radford Army Ammunition Plant (SJMRF-OP-EQ/Mr. Jim McKenna), P.O. Box 2, Radford, VA 24143-0002

SUBJECT: Draft RCRA Facility Investigation/Corrective Measures Study Report for SWMUs 35, 37, 38, and Area of Concern Q (RAAP-10), Radford Army Ammunition Plant, Virginia, July 2009

1. The US Army Center for Health Promotion and Preventive Medicine reviewed the subject document, without comment, on behalf of the Office of The Surgeon General pursuant to Army Regulation 200-1 (Environmental Protection and Enhancement). We appreciate the opportunity to review this report.

2. We concur with the recommendation of no further action at these sites as being protective of human health and the environment.

3. The document was reviewed by Mr. Dennis Druck, Environmental Health Risk Assessment Program. He can be reached at DSN 584-2953, commercial (410) 436-2953 or electronic mail, dennis.druck@us.army.mil.

EXECUTIVE SUMMARY

URS Group, Inc. (URS) conducted a Resource Conservation and Recovery Act (RCRA) Facility Investigation (RFI) at Radford Army Ammunition Plant (RFAAP) Solid Waste Management Units (SWMU) 35, 37, 38, and Area of Concern (AOC) Q, Calcium Sulfate Lagoons, located in the Main Manufacturing Area (MMA) of the RFAAP. The sites consist of four separate calcium sulfate drying beds. Due to the close proximity of SWMU 38 and AOC Q, these areas are assessed as one site for nature and extent assessment and risk assessment.

The work was conducted by URS Group, Inc. (URS) to fulfill the requirements set forth in the 2000 RCRA Corrective Action permit (USEPA 2000) as tasked by the United States Army Corps of Engineers (USACE), Baltimore District. URS performed the RFI in accordance with the Master Work Plan (MWP) developed for RFAAP and Work Plan Addendum (WPA) 020 to the MWP (URS 2003). These documents, approved by the United States Environmental Protection Agency (USEPA) Region III and the Virginia Department of Environmental Quality (VDEQ), contain the Master Quality Assurance Plan (MQAP), the Master Health and Safety Plan (MHSP), and associated project-specific addenda.

Nature and Extent Assessment

At SWMU 35, the primary site-related chemicals of potential concern (COPCs) in soil are metals, polychlorinated biphenyls (PCBs), and nitroglycerin located primarily within the drying bed. COPCs identified in groundwater at SWMU 35 were limited to manganese and chloroform, with dissolved metals and chloroform concentrations detected below their unadjusted tap water risk-based concentrations (T-RBCs) or maximum contaminant levels (MCLs).

At SWMU 37, the primary site-related COPCs in soil at SWMU 37 are metals and PCBs located within the drying bed. COPCs identified in groundwater at SWMU 37 were limited to manganese, pesticides (alpha-BHC and heptachlor epoxide), and chloroform, with dissolved metals, chloroform, and heptachlor epoxide concentrations detected below their unadjusted T-RBCs or MCLs. An MCL is not available for alpha-BHC, but as presented in Section 6.0, alpha-BHC was not identified as a risk or hazard driver in the human health risk assessment.

At SWMU 38/AOC Q, the primary site-related COPCs in soil are metals and Aroclor 1254 located within the drying bed. COPCs identified in groundwater at SWMU 38 were limited to manganese and chloroform, with chloroform concentrations detected below its MCL. As presented in Section 4.7.3, a specific site-specific source related to disposal activities for the manganese concentrations detected above the T-RBC in well 38MW3 was not identified. Manganese concentrations within material in the drying bed (87 to 550 mg/kg) were similar to manganese concentrations in soil outside the drying bed (222 to 600 mg/kg) where no indication of impacts from site use was noted (i.e., no sludge present). Manganese concentrations at the site also were within the low-to-mid range of concentrations of manganese in the background data set (16.7 to 2,040 mg/kg). The occurrence of dissolved manganese at concentrations above the T-RBC at one well location 38MW3 may be due to natural geologic conditions (i.e., weathering of bedrock containing manganese and alluvial deposition).

With regard to groundwater detections of chloroform at the sites, it is important to note that studies and groundwater investigations have shown the presence of chloroform in most groundwater samples collected at the facility regardless of location. The concentrations of chloroform detected in monitoring wells at the sites are low level concentrations below the range of chloroform levels present in the water transmitted through water lines at the facility. The sites are located downgradient of developed areas containing water lines that could be leaking, which may have been the source of chloroform. In addition, as presented in Section 6.0 chloroform was not identified as a risk driver in the human health risk assessments for the sites.

Fate and Transport Assessment

The fate and transport assessment did not identify volatilization as an important fate and transport process at the sites given the low concentrations of VOCs detected in soil and sludge. Mass transport and erosion

of COPCs contained in sludge was not observed outside of the drying beds. Significant leaching of organic and inorganic COPCs from the calcium sulfate sludge to underlying soil was not apparent from the data collected.

Groundwater samples collected from the drying bed areas did not indicate appreciable leaching of constituents detected in calcium sulfate sludge to groundwater. Although low level concentrations of chloroform were detected at SWMU 35, SWMU 37, and SWMU 38/AOC Q, chloroform was not detected in soil at the sites and chloroform was detected in upgradient wells at the sites. It is important to note that studies and groundwater investigations have shown the presence of chloroform in most groundwater samples collected at the facility regardless of location. The concentrations of chloroform detected in monitoring wells at the sites are low level concentrations below the range of chloroform levels present in the water transmitted through water lines at the facility. The sites are located downgradient of developed areas containing water lines that could be leaking, which may have been the source of chloroform. In addition, as presented in Section 6.0 chloroform was not identified as a risk driver in the human health risk assessments. At SWMU 37, data suggests the site is not the source of pesticides in groundwater since the pesticides detected in groundwater were not detected in soil at the site and pesticides were also detected in background well 37MW1. At SWMU 38, a specific site-specific source related to disposal activities for the manganese concentrations detected above the T-RBC in well 38MW3 was not identified.

Human Health Risk Assessment (HHRA)

HHRAs were performed to evaluate the potential human health effects associated with releases to soil and groundwater at the sites. Receptors evaluated included: current/future maintenance worker, hypothetical future construction worker, hypothetical future commercial worker, hypothetical future adult resident, hypothetical future child resident, and hypothetical future lifetime resident. Total carcinogenic risk calculated for each receptor was below or within USEPA's target risk range for Superfund sites (1E-06 to 1E-04, USEPA 1989) for the sites. The mean concentrations for lead in surface soil and total soil for SWMU 35 (233.6 mg/kg - surface soil and 137.1 mg/kg - total soil), SWMU 37 (121 mg/kg - surface soil and 64.05 mg/kg - total soil), and SWMU 38/AOC Q (26.61 mg/kg - surface soil and 17.63 mg/kg - total soil) were below the residential lead screening level of 400 mg/kg; therefore, additional lead modeling was not conducted for the sites. Total non carcinogenic hazards after consideration of target organs, background, and site specific conditions, for all receptors were equal to or below the USEPA reference hazard index (HI) of 1E+00 with the exception of the construction worker at each site due to aluminum (SWMU 35, SWMU 37, SWMU 38/AOCQ) and manganese (SWMU 38/AOC Q) in soil. Additional comparison of site soil concentrations to background point estimates, indicated that the sites' soil concentration for these metals were not significantly above background. The results of the human health risk assessments did not indicate a requirement for further action for the sites.

Screening Level Ecological Risk Assessment (SLERA)

A SLERA was performed to evaluate potential ecological risks associated with previous activities at the site. Direct contact and wildlife ingestion pathways were evaluated for soil. Terrestrial receptors that were evaluated included: plant communities, soil invertebrate/ microbial communities, American Robin, Red-tailed Hawk, Meadow Vole, Red Fox, and Short-tailed Shrew. The SLERA assessed risk by comparing various exposure estimates for chemicals to available toxicity reference values (TRVs) for each receptor. The relative risk was expressed as a hazard quotient (HQ). An HQ of less than 1 indicates no or negligible risk. The potential for risk increases as the HQ increases above unity. HQs were calculated for no effects range observable adverse effect levels (NOAELs) and lowest observable adverse effect levels (LOAELs). Preliminary and refined risk characterizations were conducted, with refined characterizations considering 95% upper confidence limits (UCLs) concentrations, background evaluations, and other more environmentally realistic assumptions than conservative preliminary estimates.

Based on the results of the SLERAs and risk management considerations, no need for further action is required at SWMU 35, SWMU 37, and SWMU 38/AOC Q on the basis of ecological risk.

Conclusions and Recommendation

Based on the results of the RFI, HHRAs, and SLERAs, no further action is recommended for the sites.

1.0 INTRODUCTION

This Resource Conservation and Recovery Act (RCRA) Facility Investigation (RFI) report presents the results and findings of the investigations conducted at Solid Waste Management Units (SWMUs) 35, 37, and 38, and Area of Concern (AOC) Q, Calcium Sulfate Drying Beds, located in the Main Manufacturing Area (MMA) at the Radford Army Ammunition Plant (RFAAP), Radford, Virginia (the sites). The sites consist of four separate calcium sulfate drying beds. Due to the close proximity of SWMU 38 and AOC Q, these areas are assessed as one site for nature and extent assessment and risk assessment.

The work was conducted by URS Group, Inc. (URS) to fulfill the requirements set forth in the 2000 RCRA Corrective Action permit (USEPA 2000) as tasked by the United States Army Corps of Engineers (USACE), Baltimore District. URS performed the RFI in accordance with the Master Work Plan (MWP) developed for RFAAP and Work Plan Addendum (WPA) 020 to the MWP (URS 2003). These documents, approved by the United States Environmental Protection Agency (USEPA) Region III and the Virginia Department of Environmental Quality (VDEQ), contain the Master Quality Assurance Plan (MQAP), the Master Health and Safety Plan (MHSP), and associated project-specific addenda.

This RFI investigation included: direct push soil borings, installation of monitoring wells, physical soil testing, chemical sampling of soil and groundwater, and aquifer characterization. The RFI was designed to:

- Fill data gaps from previous site investigations at the sites;
- Evaluate the nature and extent of chemicals present in soil at the sites;
- Evaluate potential releases to groundwater at the sites;
- Evaluate potential risks to human health and the environment using the physical and chemical data collected at the sites; and
- Collect data to support completion of a Corrective Measures Study (CMS) for the sites.

Section 2.0 of this report presents site background information including: site history, physical setting, and previous investigation results. The RFI field investigation program is described in Section 3.0. Sufficient data was collected for the RFI to complete a Nature and Extent of Chemicals Assessment (Section 4.0), Fate and Transport Evaluation (Section 5.0), Human Health Risk Assessment (HHRA) (Section 6.0), and a Screening Level Ecological Risk Assessment (SLERA) (Section 7.0).

The results of the risk assessments and fate and transport assessment did not indicate a requirement to complete a CMS for SWMUs 35, 37, 38, and AOC Q, and therefore, a CMS has not been prepared for this report.

THIS PAGE LEFT INTENTIONALLY BLANK

2.0 SITE BACKGROUND

A comprehensive discussion of the regional physiography, soil, geology, and groundwater at RFAAP is included in the RFAAP MWP (URS 2003) and therefore is not discussed in this report.

2.1 SWMU 35 – CALCIUM SULFATE DRYING BEDS

2.1.1 Site Description

SWMU 35 is an approximately 160 feet (ft) by 80 ft calcium sulfate drying bed located in the northeast section of the MMA at RFAAP (Figure 2-1) between SWMU 8 (east) and SWMU 10 (west). The drying bed is an enclosed depressed area (approximately 5 ft from surrounding areas). The RFAAP Installation perimeter fence is between the site and the New River located 120 ft north of the site. The land north of fence slopes steeply down to the New River, which is approximately 19 to 21 ft lower than SWMU 35 (Figure 2-2).

Structures adjacent to SWMU 35 (Figure 2-2) include a biological treatment plant and equalization basin (SWMU 10) approximately 100 ft northwest of SWMU 35, piping and appurtenances associated with SWMU 10 located southwest of SWMU 35, and two calcium sulfate concrete basin treatment areas (SWMU 8 eastern and western) with the western treatment area approximately 50 ft southeast of SWMU 35.

2.1.2 Site History

A USEPA RCRA Facility Assessment (RFA) conducted at RFAAP identified the SWMU 35 calcium sulfate drying bed as having the potential to release constituents into the environment (USEPA 1987). Beginning in the Korean War era and continuing through approximately 1980, the SWMU 35 calcium sulfate drying bed periodically received sludge removed from SWMU 8. After drying, the sludge was reportedly removed from SWMU 35 and disposed of in various locations at RFAAP (Dames & Moore 1992). SWMU 8 formerly consisted of an eastern and western lagoon and was replaced with an eastern and western concrete treatment tank that manages neutralized wastewater from the A-B Line Acidic Wastewater Treatment Plant. The neutralization process that takes place at the treatment plant is as follows:

$$Ca(OH)_2 + H_2SO_4 \rightarrow CaSO_4 + 2H_2O$$

This neutralized wastewater containing calcium sulfate flows through a series of weir gates in the SWMU 8 lagoons, causing the calcium sulfate to precipitate and settle as sludge. RFAAP reported that "sediment" from SWMU 10 was potentially deposited in SWMU 35, most likely during the early 1980s (Dames and Moore 1994).

2.1.3 Physiography

SWMU 35 is an approximately 160 ft by 80 ft calcium sulfate drying bed (Figure 2-2). The drying bed is an enclosed depressed area (approximately 5 ft lower in elevation than surrounding areas) situated at an elevation of approximately 1,699 to 1,701 ft above mean sea level (msl). The RFAAP Installation perimeter fence is between the site and the New River which is located 120 ft north of the site. The land

north of fence slopes steeply down to the New River, which is approximately 19-21 ft lower than SWMU 35.

2.1.4 Surface Water

Figure 2-3 shows surface-water drainage patterns in the site area. Based on topography, SWMU 35 drains internally (i.e., stormwater runoff does not flow out of the immediate SWMU area). During the time of the field investigation, the drying bed contained heavy vegetation. No standing water was observed within the drying bed. The New River is the major surface-water feature in the area and flows southeast approximately 120 ft north of SWMU 35. Other surface water bodies, drainage ditches, manholes, catch basins, or other flow paths are not present in the immediate vicinity.

2.1.5 Site Soil

Unison-Urban Land complex soil underlies the site area. This soil has moderate permeability and medium-to-strong acidity. Organic matter content of this soil is low to moderate. Available water capacity of the Unison soil is moderate and runoff is medium. In disturbed areas, the above soil characteristics are extremely variable. A typical profile of the Unison soil in undisturbed areas consists of a 15-inch thick surface layer of dark brown and brown loam underlain by a 43-inch thick subsoil of yellowish-red sticky and plastic clay. The substratum is red sandy clay loam below a depth of approximately 58 inches. Depth to bedrock is greater than 60 inches. Urban land consists of soil covered by streets, parking lots, buildings, and other structures (URS 2003).

One representative soil sample (35SB7 – 4 to 7 ft) collected from a 3 ft interval below the sludge layer within the drying bed was submitted for physical soil testing at URS' laboratory in Totowa, New Jersey. Test results are summarized in the following table and in Table 2-1. Complete physical test results are summarized in Appendix C.1. As indicated by the test results, this sample was classified as clayey sand (SC) with a nearly neutral pH.

Summary of Physical Soil Test Data

Test Parameter	Range of Parameter Values
Sample Depths (ft below ground surface [bgs])	4-7 ft
Unified Soil Classification Symbol	SC (Clayey Sand)
Sieve Analysis – percent (%) fines (minus 200 Sieve)	35%
Total Organic Carbon	9%
pH – distilled water	6.8
pH – 0.01 M CaCl Solution	6.3
Soil particle density (pounds per cubic foot)	2.710
Soil bulk density (pounds per cubic foot)	126.9
Soil dry density (pounds per cubic foot)	107.9
Coefficient of permeability (centimeters per second)	1.8E-06
Water Content (%)	31%

2.1.6 Site Geology

Site geologic conditions were characterized for the RFI by completing 10 direct push soil borings (10 to 18 ft bgs), installing two groundwater monitoring wells (31 ft bgs), and physical testing of one sludge sample and one soil sample. Six of the direct push borings were completed to refusal (presumed river jack gravel). The remaining four were completed to a predetermined depth of 10 ft bgs. Monitoring wells 35MW1 and 35MW2 were completed to a depth of approximately 9 ft and 5 ft beneath the overburden/bedrock interface, respectively. Monitoring well and soil boring locations are shown on Figure 2-4 and boring data are summarized in Table 2-2. Monitoring well construction data are summarized in Table 2-3 and boring logs/construction diagrams are included in Appendix C.2.

Subsurface data from site borings and monitoring wells were used to construct a geologic cross-section (Figure 2-5). Cross-section A-A' is orientated southwest to northeast across SWMU 35 in the general direction of groundwater flow.

The site area is underlain by approximately 20 to 26 ft of unconsolidated alluvial deposits, except within the drying bed area where 12 to 15 ft of alluvium underlies the bottom of the drying bed sludge. These deposits generally consist of a fining upward sequence of sediment consisting of primarily micaceous silty (SM) and sandy silt (ML) and locally a basal layer of sand and gravel (GM). Carbonate bedrock of the Cambrian Age Elbrook Formation underlies the alluvial deposits in the site area. Rock coring completed in borings at SWMU 10 located adjacent to the site indicated that the upper 10 to 15 ft of bedrock (gray to blue gray limestone) in the site area is argillaceous, variably weathered and fractured.

Within the drying bed, a calcium sulfate sludge layer was identified at boring locations 35SB6, 35SB7, 35SB9, and 35SB10 at thicknesses ranging from 4 to 6 ft.

2.1.7 Site Hydrogeology

Regional hydrogeology and general hydrogeology information for RFAAP is included in Section 3.8 of the MWP. Groundwater conditions at the site were characterized by the installation of two additional monitoring wells (35MW1 and 35MW2), obtaining water level measurements at well locations (35MW1, 35MW2, D-2, and D-4), and completion of slug tests (35MW1 and 35MW2) to provide estimates of the hydraulic conductivity of the uppermost aquifer within the screened intervals.

2.1.7.1 Occurrence of Groundwater and Groundwater Flow Direction

The uppermost zone of groundwater at the site occurs within the lower portion of alluvium and in underlying weathered and fractured bedrock (17 to 21 ft bgs). As shown on Figure 2-5 and in Table 2-3, the thickness of the saturated zone above bedrock decreases with increased distance upgradient (south) of the drying bed area. Groundwater elevation data collected during the groundwater sampling event (February 7, 2008) conducted for the RFI are summarized in Table 2-3 and shown on Figure 2-6 as a potentiometric contour map. The overall groundwater flow direction shown on Figure 2-6 is toward the north and the New River, with a hydraulic gradient of 0.021 feet per foot (ft/ft) for the groundwater flow path shown on Figure 2-6. Hydraulic gradient calculations are presented in the following table.

Hydraulic Gradient for Lateral Groundwater Flow at SWMU 35

Date	Flow Path Contour Lines	Elevation Difference (ft)	Flow Path Distance (ft)	Calculated Hydraulic Gradient (ft/ft)
2/7/2008	1691.5 ft to 1686.0 ft	5.5	266	0.021

2.1.7.2 Hydraulic Conductivity and Groundwater Flow Velocity

Rising and falling head slug tests were conducted at monitoring wells 35MW1 and 35MW2 to provide estimates of the hydraulic conductivity of well screened intervals. Slug testing methods are described in Section 3.3.5 and slug test results are summarized in the following table. Detailed analysis and calculations for the slug tests are included in Appendix C.3. Results of a slug tests conducted for upgradient well D-4 in 1990 as reported in the Verification Investigation (VI) Report for SWMUs 10 and 35 (Dames & Moore 1994) are also summarized below.

Summary of Slug Test Results for SWMU 35

Well ID	Lithology of Screened Interval	Falling Head Test (cm/sec)	Rising Head Test (cm/sec)	Appropriate Test for Well Construction	Final Hydraulic Conductivity (cm/sec)
35MW1	Alluvium/Bedrock	1.56E-03	4.64E-03	Rising Head	4.64E-03
35MW2	Alluvium/Bedrock	5.12E-03	5.48E-03	Rising Head	5.48E-03
D-4	Alluvium/Bedrock	NA	NA	NA	2.80E-03
Average Hydraulic Conductivity Value					4.31E-03

Note: NA = Not Available

Slug test analysis indicated an average hydraulic conductivity of 4.31E-03 centimeters per second (cm/sec) (12.22 ft/day) for screened interval consisting of alluvium and the uppermost portion of bedrock.

Equation 1 below was used to calculate an approximate average velocity of groundwater flow within the uppermost aquifer at SWMU 35.

(1) $V_s = Ki/n_e$

Where:

V_s = average groundwater flow (seepage) velocity (ft/day)

K = hydraulic conductivity (ft/day)

i = hydraulic gradient (ft/ft)

n_e = effective porosity (%)

The following values were substituted into Equation 1:

K =	12.22 ft/day	Average value calculated from slug tests at SWMU 35
i =	0.021 ft/ft	Average value calculated at SWMU 35
n_e =	0.25	Estimated effective porosity for sand and gravel/limestone from Freeze and Cherry 1979 page 37

Using the above values, the average calculated groundwater-flow velocity at SWMU 35 is 1.02 ft/day or 372.3 ft/year.

2.1.8 Previous Investigations

2.1.8.1 RCRA Facility Assessment – USEPA 1987

An assessment was conducted for SWMU 35 to evaluate potential hazardous waste or hazardous chemical releases and implement corrective actions, as necessary. The assessment consisted of a preliminary review and evaluation of available site information, personnel interviews, and a visual inspection of the site. Environmental samples were not collected at SWMU 35 as part of the inspection. The assessment concluded that, "no visual evidence of release from these units was observed during the April 1987 [inspection] (USEPA 1987)." However, site-specific chemical samples were required in accordance with the RFAAP 1989 RCRA permit (USEPA 2000).

2.1.8.2 Geophex Hydrogeologic and Environmental Investigation of the Equalization Basin of the [Biological] Wastewater Treatment Plant – 1990

Geophex, Ltd. performed a hydrogeologic and environmental investigation of the Biological Wastewater Treatment Plant Equalization Basin (SWMU 10), which included the installation of monitoring wells D-

3D and DG-1 (Figure 2-7), performance of pump tests, and the collection of groundwater samples. Each groundwater sample was analyzed for volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), Toxicity Characteristic Leaching Procedure (TCLP) metals, and reactivity. One sample (D-3D) was above the current adjusted USEPA Region III Tap Water Risk-based Concentration (T-RBC) for SVOC dinoseb (Dames & Moore 1994). Boring logs for the monitoring wells installed by Geophex and others are included in Appendix C.2.

2.1.8.3 Bio-Plant (SWMU 10) Environmental Site Investigation – Dames & Moore – 1991

Dames & Moore reported the results of an environmental site investigation of SWMU 10 in 1991 (Dames & Moore 1991). The site investigation was performed at SWMU 10, "to collect data in support of a construction project proposed to replace the existing equalization basin with two new tanks (Dames & Moore 1992)." The following information summarizes the investigation findings relative to SWMU 35.

One soil sample and two sludge samples (referred to as sediment samples in the previous investigation) were collected by Dames & Moore from SWMU 35 in August 1990 to assess possible sources of chemicals detected in groundwater near SWMUs 10 and 35 (Figure 2-7). Sludge samples 35SE1 and 35SE2 were collected from the upper 4 ft of sludge present within the SWMU 35 drying bed. Soil sample 35SS2 was collected from a depth of 6 ft bgs from *in situ* soil underlying the sludge at location 35SE2. The average sludge thickness encountered in the drying bed was 8 ft (Dames & Moore 1992). In August 1990, one groundwater sample was collected upgradient of SWMU 35 from monitoring well D-4 (Figure 2-7). Soil and sludge samples were analyzed for VOCs, SVOCs, Target Analyte List (TAL) metals, TCLP metals, and explosives. The groundwater sample from D-4 was analyzed for VOCs, SVOCs, and explosives.

Soil and Sludge Sample Results

Soil and sludge sample results are summarized in Table 2-4. 2,4-dinitrotoluene (DNT) was detected above the USEPA Region III carcinogenic residential risk-based concentration (R-RBC) for DNT mix in sample 35SE1. Phenanthrene was detected at a concentration above the USEPA Region III Biological Technical Assistance Group (BTAG) screening level in sample 35SE2. Chromium was detected in samples 35SE1 and 35SE2 at concentrations above the adjusted R-RBC, RFAAP background point estimate, and Draft BTAG screening level. Silver was detected in sample 35SE1 at a concentration above its adjusted R-RBC and Draft BTAG screening level (when analyzed by SW-846 Method 6010). Lead was detected above its residential and industrial action levels, background estimate, and Draft BTAG screening level in samples 35SE1 and 35SE2. Other metals were not detected at concentrations above both their background point estimates and an adjusted risk-based concentration (RBC).

Groundwater Sample Results

Groundwater sample results (August 1990) are summarized in Table 2-5 for sample D-4. VOCs and SVOCs were not detected in sample D-4. Cyclo-1,3,5,7-tetramethylene 2,4,6,8-tetranitramine; Octogen (HMX) was detected in sample D-4 at a concentration below its adjusted T-RBC.

2.1.8.4 Verification Investigation – Dames and Moore - 1992/1994

The results of a VI were reported by Dames & Moore in 1992 and 1994. The objective of the VI was to evaluate whether toxic or hazardous constituents, "are present and are, or have the potential of, migrating beyond the boundaries of the identified SWMUs (Dames & Moore 1992)." Because of their proximity, SWMU 35 and SWMU 10 were combined for activities conducted during the VI.

For SWMU 35, the VI included the collection of one additional sludge sample (35SL1) from the SWMU 35 drying bed and the collection of groundwater samples from upgradient monitoring wells D-2 and D-4, and downgradient monitoring well D-5 (Figure 2-7). Sample 35SL1 was analyzed for VOCs, SVOCs, and TCLP metals. Groundwater samples collected in 1991 were analyzed for VOCs, SVOCs, explosives, TAL metals (total and dissolved), general water quality parameters, and indicator parameters.

Groundwater samples collected in 1993 were analyzed for chromium and lead (total and dissolved), explosives, general groundwater parameters, and indicator parameters.

Sludge Sample Results

Sludge results for sample 35SL1 are summarized in Table 2-4. Chemical concentrations in sample 35SL1 were below their adjusted R-RBCs. Phenanthrene was detected at a concentration above its Draft BTAG screening level in sample 35SL1.

Groundwater Sample Results

Groundwater sample results (1991 and 1993) for SWMU 35 are summarized in Table 2-5. Total chromium was detected in samples D-2 and D-4 at concentrations above its adjusted T-RBC and above the USEPA maximum contaminant level (MCL) in sample D-4. Total lead was also detected in samples D-2 and D-4 at levels above the USEPA action level. Chromium and lead were not detected in the corresponding dissolved fractions of these samples. The elevated levels in the total fraction were attributed to sample turbidity, given that the samples were collected using a high flow purge and bailer. The concentrations of nitrite/nitrate in samples D-2 and D-5 were above its adjusted T-RBC and USEPA MCL.

2.1.8.5 Installation Assessment – EPIC Aerial Photographic Analysis – USEPA 1992

The Environmental Photographic Interpretation Center (EPIC), through the USEPA and U.S. Army Toxic and Hazardous Material Agency (USATHAMA), provided aerial photographic analysis of 42 known SWMUs at RFAAP (USEPA 1992). Aerial photographs from 1937 through 1986 were analyzed to identify features that may have represented potential groundwater or surface water constituent sources at RFAAP. USATHAMA requested photograph enlargements for six SWMUs including SWMU 35. Specifically, photograph enlargements were requested from 1971 and 1975 for SWMU 35.

The aerial photographic analysis of SWMU 35 indicated that activity was first noted at the site in 1962, where one lagoon was visible in the photograph (Figure 2-8). The SWMU 35 lagoon remained present on the 1986 photography (Figure 2-9).

2.1.8.6 Closure Documentation for SWMU 10 – ATK 1998

Closure Documentation for SWMU 10 (ATK 1998), Biological Treatment Plant Equalization Basin (VAID # VA1210020730), was submitted to the VDEQ on August 7, 1998. Based on a closure inspection and the closure certifications and report, clean closure by background comparison was achieved for all constituents, except fluoranthene. Clean closure to a residential risk-based determination was achieved for fluoranthene. Therefore, the VDEQ concurred that clean closure for soil only has been achieved for SWMU 10.

2.1.8.7 Soil Screening Report for SWMUs 8 and 36 – URS 2004

The primary objectives of this site screening investigations were to assess the current conditions of soil and calcium sulfate sludge at SWMUs 8 and 36, specifically; the presence or absence of hazardous constituents in soil and calcium sulfate sludge and to assess whether soil and calcium sulfate sludge managed during a construction project would be a RCRA hazardous waste.

Soil sampling at SWMUs 8 and 36 was necessary to properly manage excavated soil that was generated as part of a project to remove and replace the western lagoon of SWMU 8 and the SWMU 36 drying beds with an engineered tank structure. The Site Screening Investigation results assisted RFAAP with proper management of the excavated material during removal and construction and prevented the need to sample under the new tank after construction. Based upon the results and conclusions of the Soil Screening Report (URS 2004), no further action was necessary to ensure protection of human health or the environment. Decision documents concurring with no further action were approved by the USEPA and VDEQ for the sites in 2005 (URS 2005a and URS 2005b).

2.2 SWMU 37, SWMU 38, AND AOC Q – CALCIUM SULFATE DRYING BEDS

2.2.1 Site Description

SWMU 37 and SWMU 38 (Calcium Sulfate Drying Beds), and AOC Q (Calcium Sulfate Treatment and Disposal Area) are located along the New River in the northwestern section of the MMA (Figure 2-1). SWMU 37 is densely vegetated area comprising approximately 0.62 acres (Figure 2-10). It is located immediately southwest of, and adjacent to, the SWMU 9 Calcium Sulfate Settling Lagoons. SWMU 38 (see photograph inset) is a smaller, densely vegetated area comprising approximately 0.23 acres (Figure 2-10). It is located immediately north-northeast of, and adjacent to, SWMU 9. AOC Q is a densely wooded depression comprising approximately 0.076 acres (Figure 2-10). It is located immediately to the west and adjacent to the northwestern corner of SWMU 38. Each unit is surrounded by an earthen berm and has an approximate depth of 4 to 8 ft. (URS 2007a). In addition to SWMU 9, other tanks and structures near the sites include a control house for the settling lagoons and other associated piping and appurtenances. Other tanks or structures are not located in or near the site area.

2.2.2 Site History

SWMU 37 and SWMU 38 are inactive units previously used for the drying of sludge removed from SWMU 9 (USEPA 1987). SWMU 9 consists of two below-grade unlined earthen lagoons listed in the RFAAP Virginia Pollution Discharge Elimination System (VPDES) permit. These lagoons formerly received neutralized wastewater from the Acidic Wastewater Treatment Plant and now receive stormwater. The wastewater containing the calcium sulfate was gravity-fed into SWMU 9 via an underground process sewer pipe (Dames and Moore 1992). Calcium sulfate precipitated and settled in the lagoons was removed and placed in SWMU 37, SWMU 38, and AOC Q.

AOC Q was reportedly used as a sludge drying bed when SWMU 38 was full. Sludge was reportedly pumped from SWMU 38 to AOC Q via pipes that ran through a depression in the berm surrounding the drying bed (Dames and Moore 1992). However, specific diagrams or site maps were not available to verify this information. The presence of pipes was not noted during the site inspection conducted for the RCRA Facility Investigation in 1987 (USEPA 1987), during the VI investigation conducted at the site in 1992 (Dames & Moore 1992), or during subsequent site screening process (SSP) investigations. Any pipes may have been removed at the time that use of AOC Q ceased; these pipes would have been of limited length given that AOC Q is located immediately adjacent to SWMU 38.

Based on aerial photographs the drying beds were in use from sometime after 1949, likely in the early 1950's due to the use of the drying beds for sludge from SWMU 9 which began operation during the Korean War (1950-1953) (Dames and Moore 1992). SWMU 37 and SWMU 38 have been inactive since the 1980's. Activity at AOC Q appeared to cease in 1971 based on aerial photographic analysis (USEPA 1992) and observations during conduct of the RFA and VI confirmed that this disposal unit area was not in use.

2.2.3 Physiography

SWMU 37 and SWMU 38 (Calcium Sulfate Drying Beds), and AOC Q (Calcium Sulfate Treatment and Disposal Area) are located along the New River in the northwestern section of the MMA. Each unit is unlined and excavated into natural grade. The elevation at these units is approximately 1,710 ft msl. A gravel road and railroad tracks are located to the east of the sites. Dense woods surround the area to the north, south, and west where the topography slopes downward towards the New River (Figure 2-10). Each unit is surrounded by an earthen berm and has an approximate depth of 4 to 8 ft. (URS 2007a).

2.2.4 Surface Water

Figure 2-11 shows surface-water drainage patterns in the site area. Based on topography, each of the sites has internal drainage (i.e., surface runoff does not flow out of the immediate site areas). A well-defined drainage ditch is located approximately 100 ft down slope of SWMU 9 and another is located approximately 50 ft to the west of SWMU 37. Other surface water bodies, drainage ditches, manholes, catch basins, or other flow paths are not present in the immediate area. The New River is located approximately 300 to 400 ft northwest of the sites (Figure 2-11) and flows toward the northeast.

2.2.5 Site Soil

The sites are underlain by Unison-Urban land complex soil, which has moderate permeability and medium-to-strong acidity. Organic matter content of this soil is low to moderate. Available water capacity of the Unison soil is moderate and runoff is medium. In disturbed areas, the above soil characteristics are extremely variable. A typical profile of the Unison soil in undisturbed areas consists of a 15-inch thick surface layer of dark brown and brown loam underlain by a 43-inch thick subsoil of yellowish-red sticky and plastic clay. The substratum is red sandy clay loam below a depth of approximately 58 inches. Depth to bedrock is greater than 60 inches. Urban land consists of soil covered by streets, parking lots, buildings, and other structures (URS 2003).

Two representative subsurface soil samples from each site were submitted for physical soil testing at URS' laboratory in Totowa, New Jersey. Test results are summarized in the following table and in Table 2-1. Complete physical test results are summarized in Appendix C.1. The predominant soil type identified by the testing consisted of silty sand (SM) that ranges from slightly acidic to neutral, with low organic content. One sample representative of slightly finer grained material was classified as sandy clay (CL) with nearly 50% sand size particles. A representative sample of the sand and gravel layer generally present at depths greater than 20 ft was classified as sandy gravel (GP).

Summary of Physical Soil Test Data for RFI

Test Parameter	Range of Parameter Values
Sample Depths (ft bgs)	6-24
Unified Soil Classification Symbol	SM (silty sand) – 3 samples SC-SM (clayey sand-silty sand) –1 sample CL (sandy clay) - 1 sample GP (sandy gravel) – 1 sample
Sieve Analysis - % fines (minus 200 Sieve)=	3.9 to 52.6%
Organic Content	0.6 to 1.8%
pH – distilled water	5.1 to 7.1
pH – 0.01 M CaCl Solution	5.4 to 6.6
Soil particle density (pounds per cubic foot)	2.677 – 2.746
Soil bulk density (pounds per cubic foot)	116.0 to 130.1
Soil dry density (pounds per cubic foot)	97.9 to 111.9
Coefficient of permeability (centimeters per second)	1.2E-07 to 2.0E-03
Water Content (%)	3.7 to 26.4%

Borings indicate that the sites are underlain by 20 ft or more of unconsolidated soil (alluvial deposits) overlying carbonate bedrock of the Elbrook Formation. These deposits generally consist of 15 to 20 ft of silty sand (SM) with occasional sandy clay (CL) overlying silty gravel (GM) and/or gravel with silt (GP) (URS 2007a). Calcium sulfate sludge is present within SWMU 37 (2 ft thick) and AOC Q (0.5 ft thick). Sludge was not encountered within SWMU 38 at the locations sampled although it was reported present during the 1992 VI. During the RFI within the drying beds, a calcium sulfate sludge layer was identified at SMWU 37 (thickness ranging from 1 to 4.5 ft), SWMU 38 (thickness ranging from 0.25 to 0.75 ft), and at AOC Q (thickness of 0.75 ft).

2.2.6 Site Geology

In addition the soil borings and physical testing completed for the SSP, site geologic conditions were characterized for the RFI by completing 15 direct push soil borings (8 to 10 ft bgs), installing six groundwater monitoring wells (36 to 41 ft bgs), and physical testing of two soil samples from each site. Monitoring well and soil boring locations are shown on Figure 2-12 and boring data are summarized in Table 2-2. Monitoring well construction data are summarized in Table 2-3 and boring logs/construction diagrams are included in Appendix C.2.

Subsurface data from site borings and monitoring wells were used to construct two geologic cross sections. Cross-section B-B' is orientated northwest to southeast across SWMU 37 (Figure 2-13) and cross-section C-C' is orientated northwest to southeast across SWMU 38 and AOC Q, (Figure 2-14).

The area of SWMU 37, SWMU 38, and AOC Q is underlain by approximately 27 to 34 ft of unconsolidated alluvial deposits. These deposits generally consist of a fining upward sequence of sediment comprising a bottom layer of sand and gravel approximately 2 to 20 ft thick. Fine to medium, micaceous silty sand (SM) with lesser amounts of sandy silt (ML) and sandy clay (CL) is present above the gravelly zone. A 1 to 5 ft thick transitional zone of highly weathered and fractured limestone bedrock was encountered at 5 of 6 monitoring well locations between the sand and gravel layer and the underlying competent gray limestone bedrock. A sand-filled void was encountered within a fractured zone of bedrock at boring 38MW2 at a depth of 33 ft.

2.2.7 Site Hydrogeology

Regional hydrogeology and general hydrogeology information for RFAAP is included in Section 3.8 of the MWP (URS 2003). Groundwater conditions at the site were characterized by the installation of six monitoring wells obtaining water level measurements at well locations and completion of slug tests to provide estimates of the hydraulic conductivity of the uppermost aquifer within of the uppermost aquifer within the screened intervals.

2.2.7.1 Occurrence of Groundwater and Groundwater Flow Direction

The uppermost zone of groundwater at the site occurs within the lower portion of alluvium and in underlying weathered and fractured bedrock (24 to 30 ft bgs). As shown on the geologic cross-sections on Figures 2-13 and 2-14, the thickness of the saturated zone above bedrock increases with increased distance away from the New River (toward the east). Groundwater elevation data collected during the RFI (February 2008, August 2008, November 2009, and June 2010) are summarized in Table 2-3 and groundwater elevation data collected in November 2009 and June 2010 are shown on Figures 2-15 and 2-16 as potentiometric contour maps. The groundwater flow direction at SWMU 38 and AOC Q shown on these figures is primarily toward the north and northeast with a hydraulic gradient of 0.010 ft/ft for the groundwater flow paths shown. As shown in Figures 2-15 and 2-16, the groundwater flow is radial at SWMU 37. Hydraulic gradient calculations are presented in the following table.

Hydraulic Gradient for Lateral Groundwater Flow at SWMU 37

Date	Flow Path Contour Lines	Elevation Difference (ft)	Flow Path Distance (ft)	Average Calculated Hydraulic Gradient (ft/ft)
11/10/2009	1687.5 ft to 1685.0 ft	2.5	105/180	0.024/0.014
6/16/2010	1687.5 ft to 1685.0 ft	2.5	135/150	0.019/0.017

Hydraulic Gradient for Lateral Groundwater Flow at SWMU 38 and AOC Q

Date	Flow Path Contour Lines	Elevation Difference (ft)	Flow Path Distance (ft)	Calculated Hydraulic Gradient (ft/ft)
11/10/2009	1684.0 ft to 1683.0 ft	1.0	120	0.008
6/16/2010	1684.0 ft to 1683.0 ft	1.0	195	0.005

2.2.7.2 Hydraulic Conductivity and Groundwater Flow Velocity

Rising and falling head slug tests were conducted at monitoring wells 37MW1 through 37MW3 and 38MW1 through 38MW3 to provide estimates of the hydraulic conductivity of well screened intervals. Slug testing methods are described in Section 3.3.5 and slug test results are summarized in the following table. Detailed analysis and calculations for the slug tests are included in Appendix C.3.

Summary of Slug Test Results

Well ID	Lithology of Screened Interval	Falling Head Test (cm/sec)	Rising Head Test (cm/sec)	Appropriate Test for Well Construction	Final Hydraulic Conductivity (cm/sec)
37MW1	Alluvium/Bedrock	1.48E-03	1.48E-03	Rising Head	1.48E-03
37MW2	Alluvium/Bedrock	6.51E-04	5.37E-04	Rising Head	5.37E-04
37MW3	Alluvium/Bedrock	6.52E-03	5.27E-03	Rising Head	5.27E-03
38MW1	Alluvium/Bedrock	2.33E-03	1.64E-03	Rising Head	1.64E-03
38MW2	Alluvium/Bedrock	1.79E-03	2.44E-03	Rising Head	2.44E-03
38MW3	Alluvium/Bedrock	2.93E-03	3.18E-03	Rising Head	3.18E-03
Average Hydraulic Conductivity Value					2.43E-03

Slug test analysis indicated an average hydraulic conductivity of 2.43E-03 centimeters per second (cm/sec) (6.89 ft/day) for screened interval consisting of alluvium and the uppermost portion of bedrock.

The following equation was used to calculate an approximate average velocity of groundwater flow within the uppermost aquifer in the area of SWMU 37, SWMU 38, and AOC Q.

$V_s = Ki/n_e$

Where:

V_s = average groundwater flow (seepage) velocity (ft/day)
K = hydraulic conductivity (ft/day)
i = hydraulic gradient (ft/ft)
n_e = effective porosity (%)

The following values were substituted into this equation:

K =	6.89 ft/day	Average value calculated from slug tests at SWMUs 37 and 38
i =	0.010 ft/ft	Average value calculated across monitored area
n_e =	0.25	Estimated effective porosity for sand and gravel/limestone from Freeze and Cherry 1979 page 37

Using the above values, the average calculated groundwater-flow velocity at SWMU 37, SWMU 38, and AOC Q is 0.28 ft/day or 102.2 ft/year.

2.2.8 Previous Investigations

2.2.8.1 Verification Investigation – Dames and Moore 1992

In 1992, as part of a VI, Dames and Moore collected and analyzed three samples of waste (sludge) from SWMU 37, SWMU 38, and AOC Q to "evaluate whether hazardous chemical concentrations exceed[ed] the [then current] health based numbers (HBNs) in the [Facility] permit" (Dames and Moore 1992). One sample (38SL1) was collected from the top one foot of sludge present in SWMU 38. Because the calcium sulfate drying beds at SWMU 37 and Area Q were dry at the time of sampling, a 5-ft hand-auger composite hole was advanced in the central part of each bed (Figure 2-17). One sample was composited from each 5-ft hole (samples 37SL1 and QSL1) to ensure a representative sample of numerous sludge-drying episodes (Dames and Moore 1992). Waste characterization samples were analyzed for VOCs, SVOCs, and TCLP metals.

Chemical concentrations detected in samples 37SL1, 38SL1, and QSL1 were below adjusted RBCs and Draft BTAG screening levels (Table 2-6).

2.2.8.2 Installation Assessment (Air Photo Interpretation)

The 1949 photograph indicates the drying beds were not in use at this time as the area is tree covered and no depressions are evident (Figure 2-18). Activity at SWMU 37, SWMU 38, and AOC Q was first noted on a 1962 photograph (Figure 2-19). The 1962 photograph reportedly depicts a lagoon containing "possible liquid" at AOC Q. The 1971 photograph reportedly depicts AOC Q as re-vegetated (Figure 2-20). SWMU 37 and 38 reportedly consisted of one "lagoon" each, although the lagoons did not appear to contain liquid (USEPA 1992). USEPA noted that both lagoons were present on the 1986 photograph; SWMU 37 contained "a small amount of reddish liquid" and SWMU 38 appeared empty (Figure 2-21).

2.2.8.3 Site Screening Process Investigation – URS 2007a

The SSP was designed using specific human health and ecological screening processes to assess: 1) whether releases of hazardous substances, pollutants, hazardous wastes, or hazardous constituents have occurred to the environment at the sites evaluated, and 2) whether further investigation or action (i.e., risk assessment, RFI, interim action), or no further action (NFA) is appropriate at a site.

For the SSP investigation conducted September-October 2003, nine borings were advanced in and around SWMU 37, SWMU 38, and AOC Q to evaluate for the presence or absence of chemicals in soil potentially associated with sludge deposition (Figure 2-12). Three soil samples were collected from each boring and analyzed for target compound list (TCL) VOCs, TCL SVOCs, polynuclear aromatic hydrocarbons (PAHs), explosives (including nitroglycerin and pentaerythiritol tetranitrate [PETN]), and TAL metals. One selected surface soil sample for each site was also analyzed for TCL pesticides, TCL polychlorinated biphenyls (PCBs), and TCL herbicides.

Two samples (from each site) were collected for physical testing including: percent moisture, grain size, pH, total organic content (TOC), specific gravity, and bulk density. Additional testing on selected

samples was conducted for Atterberg limits and/or hydraulic conductivity. Analytical results for these samples are summarized in Appendix C.1.

Detected chemicals for the sites included the following: SWMU 37 – VOCs, SVOCs, PAHs, Aroclor 1254, dieldrin, explosives, and metals; SWMU 38 – VOCs, SVOCs, PAHs, Aroclor 1254, explosives, and metals; and AOC Q – VOCs, SVOCs, PAHs, Aroclor 1254, explosives, and metals. (Note that the COPCs identified in the SSP investigation may differ from the COPCs identified in the RFI based on updated RBC screening levels and additional soil data collected during the RFI used in the screening.)

The human health risk screening portion of the SSP consisted of the following components:

1. Identification of chemicals of potential concern (COPCs) via comparison of maximum detected concentrations (MDCs) to adjusted R-RBCs and industrial risk-based concentrations (I-RBCs);
2. Cumulative human health risk screening;
3. Chemical specific screening for lead and iron;
4. MDC comparison to soil to groundwater site screening levels (SSLs) (dilution attenuation factor [DAF] 20); and
5. Metals MDC comparison to background point estimates.

The human health risk screening resulted in the identification of the following COPCs for the sites: SWMU 37 – VOCs (SSL only), 2,4-DNT (as DNT Mixture), and metals, SWMU 38 – Aroclor 1254 and metals, and AOC Q – none.

The ecological risk screening portion of the SSP consisted of the following components:

1. Problem formulation including identification of chemicals of potential ecological concern (COPECs);
2. Exposure assessment;
3. Ecological effects assessment; and
4. Risk characterization.

The ecological risk screening portion of the SSP resulted in the identification of the following COPECs for the sites: SWMU 37 – Aroclor 1254 and metals; SWMU 38 –Aroclor 1254, fluoranthene (direct contact only), and metals, and AOC Q – none. Although fluoranthene was identified as a COPEC for invertebrates at SWMU 38, the two detections were at low concentrations slightly above the BTAG direct contact screening value resulting in hazard quotient (HQs) of 1.1 and 1.8. Since fluoranthene was not identified as a COPEC for wildlife food chain modeling and was determined to pose negligible potential risk (HQ<2) to invertebrates at SWMU 38, further investigation of SVOCs/PAHs is not proposed for the sites.

The SSP (URS 2007a) resulted in the recommendation of a focused RFI for soil and groundwater media at the sites based on detected concentrations above the site-specific SSL for trichloroethene (TCE) at SWMU 37, the lack of groundwater data for the sites, and the results of the human health and ecological risk screening. The RFI was to focus on metals, explosives (in sludge), PCBs, pesticides, and VOCs (groundwater only).

Notes:
[1] = Sample collected from calcium sulfate sludge
ft bgs = Feet below ground surface
pcf = Pounds per cubic foot
cm/sec = centimeters per second
USCS = Unified Soil Classification System
(D2216) = ASTM Test Method

SU = Standard Units
-- = Unitless
nt = Not tested
* = total organic carbon

SM = Sand with silty fines
SC = Sand with clayey fines
CL = Clay low plasticity
GP = Gravel poorly graded

Notes:

USEPA = U.S. Environmental Protection Agency
ft bgs = Feet Below Ground Surface
(A) = Facility-Wide Background Point Estimate as Reported in the Facility-Wide Background Study Report (IT 2001)
RBC = Risk-Based Concentration
USEPA Region III Risk-Based Concentration (RBC) values from the October 11, 2007, RBC Table and October 11, 2007 Alternate RBC Table
Adjusted RBCs = a Hazard Quotient (HQ) of 0.1 applied to non-carcinogens
BTAG = Biological Technical Assistance Group Screening Level (USEPA 1995)
mg/kg = Milligram Per Kilogram
TAL = Target Analyte List
VOC = Volatile Organic Compound
SVOC = Semivolatile Organic Compound
CSE = Chemicals in Sediment
CSO = Chemicals in Soil
GFAA = Graphite Furnace Atomic Absorption
ICP = Inductively Coupled Plasma
-- = No Risk Criteria Available
ND = Not Detected
NT = Not Tested
TIC = Tentatively Identified Compound
HMX = Octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine
RDX = Hexahydro-1,3,5-trinitro-1,3,5-triazine
B = Analyte was detected in corresponding method blank; values are flagged if the sample concentration is less than 10 times the method blank concentration for common laboratory constituents and 5 times for all other constituents.

= Concentration Exceeds Soil Residential RBC

bold = Concentration Exceeds Soil Industrial RBC

= Concentration Exceeds BTAG Screening Level

underline = Concentration Exceeds Site Background Values

(1) = Chromium VI RBC value was used
(2) = Lead criteria are Action Levels; see USEPA Region III guidance
(3) = Mercuric chloride soil RBC value used
(4) = RBC value for pyrene was used for these compounds

( ) = Parenthesis are used to indicate the number of unknown TICs that were detected in either the volatile or semivolatile GC/MS library scans. The number beside the parenthesis is the total concentration of all TICs detected in each respective scan

3.0 FIELD INVESTIGATION PROGRAM

3.1 SAMPLING AND ANALYSIS

The RFI sampling and analysis program is summarized in Table 3-1; this table identifies the boring locations, chemical and physical sample locations and depths, and analytical methods and parameters. Figures 3-1, 3-2, and 3-3 show the soil sample locations and the monitoring well locations for SWMU 35, SWMU 37, and SWMU 38/AOC Q, respectively.

3.1.1 Soil Borings and Soil Sampling

Direct push soil borings with chemical sampling were used to: characterize the nature and extent of constituents in soil at the sites, identify the lateral and vertical extent of calcium sulfate material present, and characterize soil lithology and depth to groundwater and/or bedrock. For the SSP and RFI investigations, ten direct push borings were completed at SWMU 35, ten direct push borings were completed at SMWU 37, eight direct push borings and two hand auger borings were completed at SWMU 38, and four direct push borings were completed at AOC Q, as summarized below and in Table 3-1.

Figures 3-1, 3-2, and 3-3 show the boring locations for SWMU 35, SWMU 37, and SWMU 38/AOC Q, respectively. The SSP and RFI soil investigations and associated samples are summarized in the following table.

Soil Sampling and Analysis for SWMU 35

Date/Event	Soil Sample Locations	Analytical Parameters	Comments
November 2007 (RFI)	***Within Drying Bed:*** 35SB5 through 35SB10	TAL Metals, TCL VOCs, TCL SVOCs, TCL PCBs, TCL Pesticides, Explosives, and Nitroglycerin/PETN	Assess the nature and extent of constituents within the drying bed. Assess extent and volume of sludge inside the drying bed.
	35COMP	Full TCLP and pH	Assess hazardous waste characteristics of sludge within the drying bed.
	Outside Drying Bed: 35SB1 through 35SB4	TAL Metals, TCL VOCs, TCL SVOCs, TCL PCBs, TCL Pesticides, Explosives, and Nitroglycerin/PETN	Assess the nature and extent of constituents outside the drying bed. Assess presence/absence of sludge outside the drying bed.

Soil Sampling and Analysis for SWMU 37

Date/Event	Soil Sample Locations	Analytical Parameters	Comments
October 2003 (SSP)	***Within Drying Bed:*** 37SB1 and 37SB2	TAL Metals, TCL VOCs, TCL SVOCs, TCL PCBs (37SB1A), TCL Pesticides (37SB1A), Explosives, and Nitroglycerin/PETN	Assess the nature and extent of constituents within the drying bed. Assess extent and volume of sludge inside the drying bed.

Date/Event	Soil Sample Locations	Analytical Parameters	Comments
	Outside Drying Bed: 37SB3	TAL Metals, TCL VOCs, TCL SVOCs, Explosives, and Nitroglycerin/PETN	Assess the nature and extent of constituents outside the drying bed. Assess presence/absence of sludge outside the drying bed.
November 2007 (RFI)	***Within Drying Bed:*** 37SB7 through 37SB10 37COMP	TAL Metals, TCL PCBs, TCL Pesticides, Explosives, and Nitroglycerin/PETN Full TCLP and pH	Assess the nature and extent of constituents within the drying bed. Assess extent and volume of sludge inside the drying bed. Assess hazardous waste characteristics of sludge within the drying bed.
	Outside Drying Bed: 37SB4 through 37SB6	TAL Metals, TCL PCBs, TCL Pesticides, Explosives, and Nitroglycerin/PETN	Assess the nature and extent of constituents outside the drying bed. Assess presence/absence of sludge outside the drying bed.

Soil Sampling and Analysis for SWMU 38

Date/Event	Soil Sample Locations	Analytical Parameters	Comments
October 2003 (SSP)	***Within Drying Bed:*** 38SB1 and 38SB3	TAL Metals, TCL VOCs, TCL SVOCs, TCL PCBs (38SB1A), TCL Pesticides (38SB1A), Explosives, and Nitroglycerin/PETN	Assess the nature and extent of constituents within the drying bed. Assess extent and volume of sludge inside the drying bed.
	Outside Drying Bed: 38SB2	TAL Metals, TCL VOCs, TCL SVOCs, Explosives, and Nitroglycerin/PETN	Assess the nature and extent of constituents outside the drying bed. Assess presence/absence of sludge outside the drying bed.
November 2007 (RFI)	***Within Drying Bed:*** 38SB7 through 38SB10 38COMP	TAL Metals, TCL PCBs, TCL Pesticides, Explosives, and Nitroglycerin/PETN Full TCLP and pH	Assess the nature and extent of constituents within the drying bed. Assess extent and volume of sludge inside the drying bed. Assess hazardous waste characteristics of sludge within the drying bed.
	Outside Drying Bed: 38SB4 through 38SB6	TAL Metals, TCL PCBs, TCL Pesticides, Explosives, and Nitroglycerin/PETN	Assess the nature and extent of constituents outside the drying bed. Assess presence/absence of sludge outside the drying bed.
	Outside Drying Bed: 38SC1 through 38SC15	Not Applicable Visual Sludge Identification	Stratigraphic borings to delineate the nature and extent of sludge identified in an area outside of the drying bed during well installation (See Section 3.4).

Soil Sampling and Analysis for AOC Q

Date/Event	Soil Sample Locations	Analytical Parameters	Comments
October 2003 (SSP)	***Within Drying Bed:*** QSB1 and QSB3	TAL Metals, TCL VOCs, TCL SVOCs, TCL PCBs (QSB1A), TCL Pesticides (QSB1A), Explosives, and Nitroglycerin/PETN	Assess the nature and extent of constituents within the drying bed. Assess extent and volume of sludge inside the drying bed.
	Outside Drying Bed: QSB2	TAL Metals, TCL VOCs, TCL SVOCs, Explosives, and Nitroglycerin/PETN	Assess the nature and extent of constituents outside the drying bed. Assess presence/absence of sludge outside the drying bed.
November 2007 (RFI)	***Within Drying Bed:*** QSB4	TCL PCBs, TCL Pesticides, Explosives, and Nitroglycerin/PETN	Assess the nature and extent of constituents within the source area. Assess extent and volume of sludge inside the drying bed.

RFI soil samples were collected from each boring within the drying beds from the following depth intervals: (1) surface, (2) immediately below sludge (if present) or intermediate depth, (3) terminal depth at specified depth. A surface soil sample was collected from the boring located outside the drying beds. As stated in WPA 020 (URS 2007), the terminal depths of the RFI borings within the drying beds of 8 ft below grade was established since additional delineation of impacted soil is not required below this depth given that concentrations of metals detected in subsurface soil samples collected from inside the drying beds are below background point estimates and the vertical organic constituent concentrations has been appropriately characterized in the SSP. In addition, the depth of the drying bed areas is 4 to 8 ft below the outside grade and therefore, samples collected from depths of 8 ft or less will provide data from the same soil strata for sample collected inside and outside of the SWMUs.

Additionally, two samples from each area were collected for physical testing of pH, TOC, grain size, Atterberg Limits (selected samples), bulk density, hydraulic conductivity, and moisture content. Refer to Table 3-1 for boring and analyses information.

One composite sample was collected from within the drying bed at each SWMU and analyzed for corrosivity (pH) and toxicity (full TCLP analysis) to assess the hazardous waste characteristics of the sludge (see Appendix C.6).

- Sludge samples had pH levels in the range of 7.5 to 7.9 and therefore this material does not exhibit the characteristic of corrosivity as defined in 40 CFR §261.22 (USEPA 2010);
- TCLP levels of sludge samples are below regulatory limits specified in 40 CRF §261.24 (USEPA 2010), and therefore this material does not exhibit the characteristic of toxicity;
- TCLP detections are limited to low levels of barium, silver, and chromium (one sample) at levels approximately three orders of magnitude below regulatory limits; and
- Explosives and cyanide are present in some of the sludge samples at low concentrations below human health risk-based screening levels and therefore this material does not exhibit the characteristic of reactivity as defined in 40 CFR §261.23 (USEPA 2010).

3.1.2 Monitoring Well Installation and Groundwater Sampling

In December 2007, monitoring wells 35MW1 and 35MW2 were installed at SWMU 35 (Figure 3-1), monitoring wells 37MW1, 37MW2, and 37MW3 were installed at SWMU 37 (Figure 3-2), and monitoring wells 38MW1, 38MW2, and 38MW3 were installed at SWMU 38/AOC Q (Figure 3-3) to evaluate potential releases to groundwater. A groundwater sampling event was completed at the sites in February 2008. Based on the results of the initial groundwater sampling event, additional confirmation groundwater sampling was conducted in June 2008 for pesticides at monitoring well 37MW2 and for manganese at 38MW3. An additional groundwater well was installed in May 2010 to assess groundwater flow in the SWMU 37 area and sampled in June 2010 for VOCs to assess migration of VOCs from soil to groundwater. The groundwater sampling analytical parameters are summarized below and in Table 3-1. Monitoring well construction data are summarized in Table 2-3.

Monitoring Well Sampling and Analysis (February 2008)

Site	Monitoring Wells Sampled	Analytical Parameters
SWMU 35	35MW1 (D), 35MW2 (D), D-2 (U), and D-4(U)	TAL metals (total and dissolved), TCL pesticides, TCL PCBs, TCL VOCs, TCL SVOCs, explosives with nitroglycerin, and perchlorate. Field water quality parameters: pH, temperature, specific conductance, dissolved oxygen, oxidation-reduction potential (ORP), and turbidity.
SWMU 37	37MW1 (U), 37MW2 (D), and 37MW3 (D)	TAL metals (total and dissolved), TCL pesticides, TCL PCBs, TCL VOCs, explosives with nitroglycerin, and perchlorate. Field water quality parameters: pH, temperature, specific conductance, dissolved oxygen, ORP, and turbidity.
SWMU 38/ AOC Q	38MW1 (C), 38MW2 (D), and 38MW3 (D)	TAL metals (total and dissolved), TCL pesticides, TCL PCBs, TCL VOCs, explosives with nitroglycerin, and perchlorate. Field water quality parameters: pH, temperature, specific conductance, dissolved oxygen, ORP, and turbidity.

Note: (U) = Upgradient, (D) = Downgradient, and (C) = Crossgradient

Monitoring Well Sampling and Analysis (June 2008)

Site	Monitoring Wells Sampled	Analytical Parameters
SWMU 37	37MW2 (D)	TCL pesticides
SWMU 38/ AOC Q	38MW3 (D)	Manganese (total and dissolved)

Note: (D) = Downgradient

Monitoring Well Sampling and Analysis (June 2010)

Site	Monitoring Wells Sampled	Analytical Parameters
SWMU 37	37MW4 (D)	TCL VOCs

Note: (D) = Downgradient

3.1.3 Aquifer Testing

Rising head and falling head slug tests were conducted in monitoring wells 35MW1, 35MW2, 37MW1 through 37MW3, and 38MW1 through 38MW3 to assess hydraulic conductivity of the screened intervals of the uppermost aquifer at the site. Aquifer test data and analysis are presented in Appendix C.4 and results are discussed in Sections 2.1.7.1 and 2.2.7.1 for SWMU 35 and SWMUs 37, 38 and AOC Q, respectively. Slug test methods are discussed in Section 3.3.5.

3.2 QUALITY ASSURANCE

Quality Assurance (QA) planning defined the overall system of activities for assuring the reliability of data produced. The system integrated the quality planning, assessment, and corrective actions of various groups in the organization to provide the independent QA program necessary to establish and maintain an effective system for collection and analysis of environmental samples and related activities. The program encompasses the generation of complete data with its subsequent review, validation, and documentation.

The accuracy and integrity of RFI data were ensured through the implementation of internal quality control (QC) measures consistent with MWP Addendum 020 (URS 2007c). QA and QC procedures, including field QC, laboratory QC, data management, and data validation, were integrated into the investigation program to meet data quality objectives (DQOs) established and approved for the RFI. The data were evaluated for each of the DQO indicators and the results of this evaluation are presented in Appendix G.1. DQOs for the RFI were met.

3.3 INVESTIGATION METHODOLOGY

3.3.1 Soil Sampling for Chemical Analysis

Surface and subsurface soil samples were collected for chemical analysis following the procedures outlined in standard operating procedure (SOP) 30.1 included in Appendix B and as described in Section 5.2 of the MWP (URS 2003).

The soil core interval was examined and classified by the site geologist and recorded in the field logbook and on the boring log consistent with SOPs 10.1 and 10.3, respectively (Appendix B). Soil was then extracted from the appropriate interval; sample containers were filled, labeled, and placed into coolers with ice and maintained at 4 degrees Celsius (°C).

Soil samples were collected from the borings using a tractor-mounted direct push rig (Geoprobe®) and skid steer mounted direct push rig. These rigs were equipped with 1.25-inch diameter push rods, 4-ft long, 2-inch diameter, stainless steel closed solid barrel sampler (Macro-Core®) with a disposable liner and stainless steel cutting shoes. A percussion hammer was used to advance the sampling assembly. Following withdrawal of the Macro-Core® and removal of the liner, a cutting device was used to open the liner before inspection and processing of the sample cores. Soil sampling field data sheets are included in Appendix C.4.1.

Once the termination depth of the boring was reached and sample collection was completed, the borehole was backfilled with hydrated bentonite chips. Excess soil cuttings were temporarily accumulated in 55-gallon drums at the Installation-approved area for disposal as discussed in Section 3.3.7. Soil boring logs are included in Appendix C.2.1.

3.3.2 Monitoring Well Installation and Development

Monitoring wells 35MW1, 35MW2, 37MW1, 37MW2, 37MW3, 37MW4, 38MW1, 38MW2, and 38MW3 were installed following the procedures outlined in SOP 20.1 (Appendix B) and as described in Section 5.2 of the MWP (URS 2003). These monitoring wells were installed using a truck or track mounted drill rig using 4.25-inch inner diameter hollow stem augers for overburden drilling and a 4-inch diameter air rotary drill bit for drilling into bedrock. Boring logs were completed as described in SOP 10.3 and drilling activities were documented in the field logbook as described in SOP 10.1 (Appendix B). Downhole drill rig tools and equipment were decontaminated before use at each location following SOP 80.1 (Appendix B).

Monitoring wells were constructed with 2-inch diameter, Schedule 40 polyvinyl chloride (PVC) 0.01-inch factory slotted screen and riser pipe with threaded joints. Each monitoring well was screened across the overburden and bedrock interface to monitor the uppermost zone of groundwater at the site. Boring logs and construction diagrams for the monitoring wells are included in Appendix C.2.2. Monitoring well construction data are summarized in Table 2-3.

Prior to sampling, each of the monitoring wells was developed consistent with SOP 20.2 (Appendix B) and as described in Section 5.2 of the MWP (URS 2003) by using a surge block, disposable bailer, and stainless steel, adjustable flow rate submersible pump with new disposable tubing. Development was continued at each monitoring well until a minimum of three equivalent well volumes were purged, water quality indicator parameters had stabilized, development water was clear to the unaided eye, and any remaining sediment had been removed from the well. Well development field data sheets are provided in Appendix C.4.2.

3.3.3 Groundwater Sampling

Groundwater samples were collected for chemical analysis in accordance with SOP 30.2 (Appendix B) and as described in Section 5.2.10 of the MWP (URS 2003). Groundwater sampling information was recorded in the field logbooks as described in SOPs 10.1 and 10.2 (Appendix B). Groundwater sampling field data sheets are included in Appendix C.4.3.

Low flow purging and sampling techniques were used to collect the groundwater samples from the permanent monitoring wells following the procedure outlined in Section 3.3 of SOP 30.2 (Appendix B). Equipment used to purge and sample wells was thoroughly decontaminated before and after use following SOP 80.1 (Appendix B). All equipment used for monitoring water quality parameters was calibrated before use according to the manufacture's instructions and SOP 40.1 (Appendix B). Prior to the sampling round, the depth to water was measured at each well to the nearest 0.01 ft using an electronic water level indicator in accordance with SOP 40.2. Calibration and measurement data were recorded in the field logbook.

A stainless steel, adjustable flow rate submersible pump and/or a peristaltic pump, and new disposable tubing were used to collect the groundwater samples. The pump tubing was connected to an in-line flow-through cell and the multi-parameter meter probe was connected to the flow cell to monitor water quality parameters during purging. The standing water columns at the time of sampling in the RFI wells at SWMUs 35, 37, and 38/Q ranged from approximately 10 to 15 feet, with the exception of 38MW3, which had a standing water column of approximately 18 feet. Pumping was started at the mid point of the water column and the pump rate was adjusted to cause minimal drawdown (less than 0.2 ft if possible). A Horiba Model U-22 multi-parameter water quality meter was used to monitor pH, specific conductance, temperature, ORP, dissolved oxygen, and turbidity during purging. Purging was continued until parameter stabilization was achieved. Once purging was complete, the pumping rate was reduced to its lowest steady rate and the in-line flow cell was disconnected from the tubing to allow for sampling from the tubing directly into sample containers provided the laboratory.

Groundwater samples were collected and containerized in the order of volatilization sensitivity of the parameters. Filtered and unfiltered samples were collected for metals analysis. Metals samples were filtered with an in-line high capacity 0.45-micron disposable filter. The appropriate sample containers were filled, labeled, and placed into coolers with ice and maintained at 4 °C.

3.3.4 Water Quality Measurements

Field water quality measurements were collected consistent with SOP 40.1 (Appendix B) using a Horiba Model U-22 multi-parameter water quality meter. Prior to its use each day, the meter was calibrated according to the manufacturer's instructions.

3.3.5 Aquifer Tests

Rising head and falling head slug tests were conducted at monitoring wells 35MW1, 35MW2, 37MW1 through 37MW3, and 38MW1 through 38MW3 in accordance with SOP 40.3 (Appendix B) and Section 5.9 of the MWP (URS 2003). A 3-inch diameter and 4-ft long solid PVC slug was used for the slug tests to induce instantaneous changes in water levels. Water level changes were recorded using a downhole pressure transducer with an internal data logger (*Insitu* Minitroll Standard P 30 pounds per square inch [PSI]). Slug-test data analysis was performed using AQTESOLV for Windows Pro Version 3.0. Appendix C.3 includes the slug test output and analysis.

3.3.6 Site Surveying

Draper Aden Associates surveyed the locations and vertical elevations for each of the monitoring wells at the sites as part of the RFI. URS surveyed the locations of soil borings and direct push groundwater borings obtained using Trimble Pathfinder Pro XRS® global positioning system (GPS) equipment.

Surveying was conducted using the U.S. State [Virginia (South Zone)] Plane Coordinate System (measured in U.S. survey ft) using the North American Datum 1983. Vertical elevations at the site were surveyed to the nearest 0.01 ft using the National Vertical Datum of 1988. Sample location coordinates and elevations are presented on Table 2-2.

3.3.7 Investigation-Derived Material (IDM) Management

IDM management activities were conducted consistent with the procedures outlined in WPA 020 (URS 2007c) and documented in the field logbook, and conducted as described below.

3.3.7.1 Accumulation

IDM accumulated during field sampling activities included the following materials and containers:

- Soil cuttings – Seventeen (17) 55-gallon drums;
- Personal protective equipment (PPE), probe liners, and plastic sheeting – Three (3) 55-gallon drums; and
- Decontamination and purge water – Sixteen (16) 55-gallon drums.

IDM accumulation and labeling was conducted as outlined in MWP SOP 70.1 (Appendix B). Drums were transferred to the Installation's approved container accumulation area at SWMU 17.

3.3.7.2 Material Characterization

Separate IDM characterization samples were collected from the soil cuttings and the drummed decontamination water. The analytical results for the IDM characterization samples indicated the soil cuttings and the decontamination water were non-hazardous material. IDM sample results are provided in Appendix C.5.

3.3.7.3 Transportation and Disposal

Before disposal, waste analytical results were provided to the Installation, IDM management subcontractor, and the disposal facilities for review and approval. Manifests were reviewed and signed by Installation personnel before loading and transport of the IDM. The Installation maintains a record of the manifests and related information including analytical testing results and waste profiles.

Freehold Cartage, Inc. and First Piedmont Corporation transported the non-hazardous soil IDM to the First Piedmont Corporation Landfill in Chatham, Virginia.

3.3.7.4 Decontamination Water

Following the waste characterization sample analysis, the Installation and RFAAP Process Water Treatment Plant engineers were provided a copy of the water IDM sample results and groundwater sample results. After receiving Plant approval, decontamination water and purge water were discharged into the collection system of the Process Water Treatment Plant.

3.4 WORK PLAN FIELD CHANGES

Cyanide analysis was not performed during the RFI soil sampling event as specified in the workplan. The laboratory analysis for Target Analyte List (TAL) inorganics did not include cyanide. Cyanide analysis was performed on 27 soil samples collected at SWMUs 37 and 38/Q for the SSP. Four of these samples were collected from calcium sulfate sludge contained in the drying beds. Cyanide was not identified as a COPC in soil or sludge due to the low level detections (0.296 to 2.2 mg/kg) at concentrations 2 to 3 orders of magnitude below the adjusted risk-based screening levels. Based on representative results of sludge samples at these sites, cyanide is not considered a constituent of concern for these disposal areas and therefore, the lack of additional cyanide data for the RFI is not considered a significant data gap.

Although the work plan indicated that soil samples were to be analyzed for PAHs via SW-846 Method 8310, since the approval of the work plan a method of SW-846 8270 to detect low level SVOCs (including PAHs) has been developed and is used for samples at the facility. This low-level SW-846 method has certain advantages over Method 8310 including more reliability in identifying target PAH compounds with comparable detection limits to Method 8310.

Monitoring well locations 38MW1 and 38MW2 were offset from their planned locations due to access constraints. Background monitoring well 38MW1 was moved to 135 feet west of its original planned location due to heavily wooded conditions to a location approximately 150 feet east of the drying bed. Monitoring well 38MW2 was moved approximately 75 ft south of its original planned location at a similar position outside of the drying bed also due to heavily wooded conditions. The monitoring well offsets did not have a significant effect on the planned assessment of groundwater conditions at SWMU 38/AOC Q because the offset locations were in the same relative position to the drying beds as originally proposed. In addition, the work plan indicated that monitoring wells would be installed with a 15-ft screen but some wells (37MW1 and 38MW3) have screens that are up to 25 ft in length. Given that the monitoring wells were installed during a period of a prolonged drought, additional screen length was installed above the water levels encountered during drilling to ensure that the top of the screen would be above seasonally high groundwater levels in the future.

During well installation at SWMU 38, a limited area of calcium sulfate sludge was identified outside of the SWMU 38 drying bed. Fifteen additional stratigraphic soil borings were completed with a hand auger to delineate the lateral and vertical extent of sludge in this area. As presented on Figure 3-3, three inches of sludge was identified in an approximately 500 square foot area located east of SWMU 38.

Due to radial groundwater flow at SWMU 37, an additional well (37MW4) was installed southeast of the SWMU to assess groundwater flow in the SWMU 37 area. The well also was sampled in June 2010 for VOCs to assess migration of VOCs from soil to groundwater.

4.0 NATURE AND EXTENT OF CHEMICALS

The following sections discuss the results of chemical sampling of soil and groundwater at the sites and assess the nature and extent of detected chemicals in site media. Chemical results are evaluated with respect to the following: USEPA Region III R-RBCs and I-RBCs for soil, and T-RBCs for groundwater (USEPA 2007a), which are adjusted downward for non-carcinogenic chemicals to an HQ of 0.1 to account for potential additive toxicity effects of multiple chemicals; USEPA Region III SSLs, DAF 20 (default values); the most current USEPA Region III ecological soil screening levels (as presented in Section 7.0); USEPA MCLs for groundwater; and facility-wide background concentrations for metals in soil as provided below (IT 2001).

Facility-Wide Point Estimates for Soil

Chemical	Minimum Concentration (mg/kg)	Maximum Concentration (mg/kg)	95% Upper Tolerance Limit (UTL) of the Mean (mg/kg)
Aluminum	3,620	47,900	40,041
Arsenic	1.2	35.9	15.8
Barium	23.4	174	209
Beryllium	0.61	5.4	1.02
Cadmium	0.62	2.5	0.69
Chromium	6.3	75.8	65.3
Cobalt	5.9	130	72.3
Copper	1.6	38.7	53.5
Iron	7,250	67,700	50,962
Lead	2.1	256	26.8
Manganese	16.7	2,040	2,543
Mercury	0.038	1.2	0.13
Nickel	4.6	94.2	62.8
Thallium	1.3	5	2.11
Vanadium	12.2	114	108
Zinc	4.7	598	202

Note: mg/kg = Milligram per kilogram

With the exception of metals in soil, chemicals detected in one or more samples in a given medium at concentrations above their adjusted RBCs, SSL DAF20s, or ecological screening levels are identified in the nature and extent assessment as COPCs. Metals in soil detected at concentrations above their background point estimates and an adjusted RBC, SSL DAF20, or ecological screening value are retained as COPCs in the nature and extent assessment. The facility-wide background concentrations are used in the nature and extent assessment to evaluate the significance of background concentrations in soil and to assist in bounding the lateral and vertical extent of metals concentrations potentially attributable to historical site activities. Additional chemical specific screening information is provided below.

Note that for some explosives (i.e., DNT), the carcinogenic toxicity data available for DNTs (i.e., 2,4-DNT and 2,6-DNT) applies to the DNT mixture; therefore, the concentrations detected for 2,4-DNT and

2,6-DNT for each sample are summed and this value is screened against the carcinogenic RBC. Non-carcinogenic RBCs are available for both 2,4-DNT and 2,6-DNT; therefore, they are screened independently against the adjusted non-carcinogenic RBCs. If one compound is detected in the sample and the other compound is not, one half the detection limit of the non-detect is averaged with the detected result.

Note that if a constituent was measure by two methods, results from the more sensitive analytical method were used for screening. For example if explosives were analyzed as part of the SVOC method (Method 8270C), as well as, by an explosives specific method (Method 8330), the results from the explosives specific method were used.

4.1 NATURE AND EXTENT – SWMU 35 SOIL

4.1.1 Analytical Results

Ten surface soil samples and 12 subsurface soil samples for a total of 22 samples were collected for chemical analysis from SWMU 35 (Figure 3-1 and Table 3-1). Soil samples for chemical analysis were collected from borings from up to three intervals including: a surface soil sample ("A" sample), immediately below sludge (if present) or intermediate sample ("B" sample), and a terminal depth sample ("C" sample). Table 4-1 presents analytical results for chemicals detected in soil samples collected at SWMU 35 and screens these data with respect to adjusted RBCs, SSLs, and background concentrations. Table 4-2 summarizes the screening results for soil data including: constituents detected, minimum and maximum concentrations detected, number of detections, number of samples, and number of samples above human health screening criteria or SSL DAF20 screening levels and background concentrations (inorganics only). COPECs listed below were identified for the site as part of the refined screening level ecological risk assessment presented in Section 7.2.3 and above background point estimates (inorganics only). The screenings resulted in the identification of the following COPCs and COPECs (note that chemicals which were below background point estimates but were identified as hazard drivers for the HHRA are italicized):

TAL Metals (Methods 6010B, 6020A, 7471A) – 23 TAL metals were detected in soil samples with the following metals detected at concentrations above screening levels:

RBC – *aluminum*, chromium, lead;
SSL – chromium; and
Eco – calcium, chromium, lead, and mercury.

TCL Pesticides (Method 8081A) – 2 pesticides were detected in soil samples with the following pesticides detected at concentrations above screening levels:

RBC – none;
SSL – none; and
Eco – none.

TCL PCBs (Method 8082) – 2 PCBs were detected in soil samples with the following PCBs detected at concentrations above screening levels:

RBC – Aroclor 1254 (above R-RBC and I-RBC), Aroclor 1260;
SSL – Aroclor 1254; and
Eco – none.

TCL VOCs (Method 8260B) – 8 VOCs were detected in soil samples with the following VOCs detected at concentrations above screening levels:

RBC – none;
SSL – none; and
Eco – none.

TCL SVOCs (Method 8270C) – 17 SVOCs were detected in soil samples with the following SVOCs detected at concentrations above screening levels:

RBC – none;
SSL – none; and
Eco – none.

Explosives (Method 8330) and Nitroglycerin (Method 8332) – 3 explosives and nitroglycerin were detected in soil samples with the following constituents detected at concentrations above screening levels:

RBC – nitroglycerin (above R-RBC and I-RBC);
SSL – none; and
Eco – none.

4.1.2 Human Health Nature and Extent Assessment

A summary of the human health risk and background screening results for COPCs is presented in the table below.

Summary of COPCs for Soil

Chemical	Total # of Det/# of Samples	Above Adjusted R-RBC		Above Adjusted I-RBC	
		# Above.	Sample IDs	# Above.	Sample IDs
Aluminum*	22/22	0	NA	0	NA
Chromium	22/22	5	35SB5A DUP AVG, 35SB6A, 35SB7A, 35SB9A, 35SB10A	0	NA
Lead	22/22	2	35SB7A, 35SB9A	0	NA
Aroclor 1254	17/22	8	35SB2A, 35SB3A, 35SB5A DUP AVG, 35SB6A, 35SB7A, 35SB8A, 35SB9A, 35SB10A	1	35SB6A
Aroclor 1260	1/22	1	35SB6A	0	NA
Nitroglycerin	1/22	1	35SB6A	1	35SB6A

Notes: NA=Not Applicable, DUP AVG = Duplicate Average, *No sample concentrations were above the background point estimate for aluminum but aluminum was identified as a hazard driver in human health risk assessment

The nature and extent of COPCs identified in the above table, as well as constituents with concentrations above SSL DAF20s (above background concentrations for inorganics) identified in Section 4.1.1 and presented on Table 4-2, is discussed further in the following sections.

4.1.2.1 Aluminum

Aluminum was detected at concentrations above its R-RBC but below its background point estimate and adjusted I-RBC in all samples collected. Although aluminum was not detected at concentrations above its background point estimate, it was identified as a hazard driver for the construction worker in the HHRA; therefore, aluminum is included in the nature and extent assessment for the site (Figure 4-1). Detected aluminum concentrations within the drying bed (12,000 to 25,000 mg/kg) were similar to detected aluminum concentrations outside the drying bed (19,000 to 23,000 mg/kg) where no indications of impacts from site use were noted (i.e., no sludge present). The detected concentrations also were within the mid-range of detected concentrations of aluminum in the background data set (3,620 to 47,900 mg/kg). An SSL DAF20 is not available for aluminum, but the groundwater sample results did not indicate the leaching of aluminum from soil to groundwater at concentrations above its adjusted T-RBC.

4.1.2.2 Chromium

Chromium was detected at concentrations above its R-RBC and background point estimate in five surface soil/sludge samples collected within the drying bed. Detected concentrations in these samples were below the adjusted I-RBC. Detected chromium concentrations in samples collected from 1 foot below the sludge to the boring termination depths were below the R-RBC and background point estimate indicating the vertical extent of concentrations above the adjusted R-RBC and background point estimate is limited to the sludge material and depths less than 6 ft bgs (Figure 4-1). Although five surface soil/sludge samples collected within the drying bed were above chromium's SSL DAF20, the subsurface soil sample results did not indicate leaching of chromium from the sludge to underlying soil at levels above the SSL DAF20 or the background point estimate (Figure 4-2). In addition, groundwater sample results did not indicate the leaching of chromium from soil to groundwater at concentrations above its adjusted T-RBC.

4.1.2.3 Lead

Lead was detected at concentrations above its residential action level (AL) and background point estimate in two surface soil/sludge samples collected within the drying bed. Detected concentrations in these samples were below the industrial AL. Detected lead concentrations in samples collected from 1 foot below the sludge to the boring termination depths were below the residential AL and background point estimate indicating the vertical extent of concentrations above the AL and background point estimate is limited to the sludge material and depth less than 6 ft bgs (Figure 4-1). An SSL DAF20 is not available for lead, but the groundwater sample results did not indicate the leaching of lead from soil to groundwater at concentrations above its action level (15ug/L).

4.1.2.4 Pesticides

Pesticides were detected in samples at concentrations below their adjusted RBCs and SSL DAF20s.

4.1.2.5 PCBs

Aroclor 1254 was detected at concentrations above its adjusted R-RBC in 8 of 22 soil samples. These detections above its adjusted R-RBC are limited to surface soil or sludge. For sample 35SB6A, the Aroclor 1254 concentration was above its adjusted I-RBC and the Aroclor 1260 concentration was above its adjusted R-RBC. The vertical extent of detected concentrations of PCBs above adjusted RBCs is limited to surface soil/sludge within the drying bed and depths less than 6 ft bgs (Figure 4-1).

PCB detections above their SSL DAF20 were limited to one sample (35SB6A) for Aroclor 1254, which was located in surface soil/sludge within the drying bed. Groundwater sample results did not indicate leaching of PCBs from soil to groundwater at detectable levels. Additional discussion and assessment of the soil-to-groundwater migration pathway is presented in Section 4.1.3.

4.1.2.6 VOCs

VOCs were detected in samples at concentrations below their adjusted RBCs and SSL DAF20s.

4.1.2.7 SVOCs

SVOCs were detected in samples at concentrations below their adjusted RBCs and SSL DAF20s.

4.1.2.8 Explosives

Explosives were detected in samples at concentrations below their adjusted RBCs and SSL DAF20s with the exception of nitroglycerin, which was detected in one sample (35SB6A) at a concentration above its adjusted R-RBC and I-RBC. Nitroglycerin was not detected in the sample collected below sample 35SB6A and the sludge; and therefore, the vertical extent of detectable concentrations of nitroglycerin is less than 6 ft bgs at this location. An SSL DAF20 is not available for nitroglycerin, but the groundwater sample results did not indicate the leaching of nitroglycerin from soil to groundwater at detectable concentrations.

4.1.3 Soil-to-groundwater Migration Assessment

As previously discussed in Section 4.1.1 and presented on Table 4-2, the concentrations for each detected chemical at the site were screened against the SSL DAF20 and background point estimate resulting in the identification of the following SSL COPCs: chromium and Aroclor 1254. Sample concentrations that were above SSL DAF20s and background point estimates (inorganics only) are summarized in the table below:

Chemical	Total # of Det/ # of Samples	# of Samples Above SSL DAF20	Sample Identification
Chromium	22/22	5	35SB5A DUP AVG, 35SB6A, 35SB7A, 35SB9A, 35SB10A
Aroclor 1254	17/22	1	35SB6A

Although chromium was detected at a concentration in one or more surface samples above its SSL DAF20 and background point estimate, chromium was not detected in subsurface soil samples collected below the sludge at concentrations above its SSL DAF20 or in groundwater samples at levels above its adjusted T-RBC. Chromium concentrations above its SSL DAF20 are presented on Figure 4-2.

While SSL exceedances indicate a theoretical potential for impact to groundwater, empirical evidence in the form of actual groundwater chemical data, soil boring characterization and chemical analyses, soil characteristics/chemistry, and fate and transport analysis offer more concrete evidence of site conditions and potential impact to groundwater. Given the age of the sludge in the drying bed (>20 years), the high organic content within the sludge, limited detection of Aroclor 1254 above its SSL, no detections in the subsurface soil above SSLs, the lack of detections in groundwater for Aroclor 1254, and the lack of detections in groundwater of chromium at concentrations above its adjusted T-RBC, these chemicals are not a concern at the site with respect to migration from soil to groundwater. Additional fate and transport information for these chemicals is provided in Section 5.1.4.

4.1.4 Ecological Nature and Extent Assessment

As presented in Section 7.2.3, after consideration of the results of the SLERA, background concentrations, site conditions, and nature of the material in place at the site, the scientific management decision point (SMDP) is the following:

There is adequate information to conclude that ecological risks are negligible and therefore there is no need for further action at the site on the basis of ecological risk.

4.2 NATURE AND EXTENT – SWMU 35 GROUNDWATER

4.2.1 Monitoring Well Analytical Results

Monitoring well sample results from wells 35MW1, 35MW2, D-2, and D-4, collected in February 2008, are summarized in Table 4-3. Table 4-4 summarizes the screening results for groundwater data including: constituents detected, minimum and maximum concentrations detected, number of detections, number of samples, and number of samples above human health screening criteria. Figure 4-3 shows the monitoring well locations and sample results for COPCs identified from the risk screening. The screening resulted in the identification of the following COPCs:

TAL Metals (Methods 6010B, 6020A, 7470A) – 18 TAL metals were detected in groundwater at concentrations below their adjusted T-RBCs with the exception of manganese (total and dissolved).

TCL Pesticides (Method 8081A) – 2 pesticides were detected in groundwater below their adjusted T-RBCs.

TCL PCBs (Method 8082) – PCBs were not detected in groundwater.

TCL VOCs (Method 8260B) – 2 VOCs were detected in groundwater at concentrations below their adjusted T-RBCs and MCLs with the exception of chloroform which was above its T-RBC but was below the MCL for total trihalomethanes (THMs).

TCL SVOCs (Method 8270C) – 7 SVOCs were detected in groundwater at concentrations below their adjusted T-RBCs.

Explosives (Method 8330) and Nitroglycerin (Method 8332) – 1 explosive (HMX) was detected in groundwater at a concentrations below its adjusted T-RBC. Nitroglycerin was not detected in groundwater.

Perchlorate (Method 6850) – Perchlorate was detected in groundwater at concentrations below its adjusted T-RBC.

4.2.2 Human Health Nature and Extent Assessment

The groundwater risk screening identified manganese and chloroform as COPCs for groundwater. The nature and extent of these COPCs in groundwater is discussed below and presented on Figure 4-3:

Manganese

Dissolved manganese was detected at a concentration above its adjusted T-RBC of 73 micrograms per liter (µg/L) in the sample collected from well 35MW1 (91 µg/L). Dissolved manganese was also detected in upgradient well D-2 at concentration of 160 µg/L. Detected concentrations were below its unadjusted T-RBC of 730 µg/L.

Chloroform

Chloroform was detected at a concentration above its T-RBC of 0.155 µg/L in the sample collected from well 35MW1 (0.36 µg/L). Chloroform was also detected in upgradient well D-4 at concentration of 13 µg/L. Detected concentrations were below the MCL of 80 µg/L for THMs.

4.3 NATURE AND EXTENT – SWMU 37 SOIL

4.3.1 Analytical Results

Ten surface soil samples and 14 subsurface soil samples for a total of 24 samples were collected for chemical analysis from SWMU 37 (Figure 3-2 and Table 3-1). Soil samples for chemical analysis were collected from borings from up to three intervals including: a surface soil sample ("A" sample), immediately below sludge (if present) or intermediate sample ("B" sample), and a terminal depth sample ("C" sample). Table 4-5 presents analytical results for chemicals detected in soil samples collected at SWMU 37 and screens these data with respect to adjusted RBCs, SSLs, and background concentrations. Table 4-6 summarizes the screening results for soil data including: constituents detected, minimum and maximum concentrations detected, number of detections, number of samples, and number of samples above human health screening criteria or SSL DAF20 screening levels and background concentrations (inorganics only). COPECs listed below were identified for the site as part of the refined screening level ecological risk assessment presented in Section 7.3.3 and above background point estimates (inorganics only). The screenings resulted in the identification of the following COPCs and COPECs (note that chemicals which were below background point estimates but were identified as hazard drivers for the HHRA are italicized):

TAL Metals (Methods 6010B, 6020A, 7471A) – 23 TAL metals were detected in soil samples with the following metals detected at concentrations above screening levels:

RBC – *aluminum*, chromium, mercury;
SSL – chromium; and
Eco – calcium, chromium, copper, and mercury.

TCL Pesticides (Method 8081A) – 2 pesticides were detected in soil samples with the following pesticides detected at concentrations above screening levels:

RBC – none;
SSL – dieldrin; and
Eco – none.

TCL PCBs (Method 8082) – 1 PCB was detected in soil samples with the following PCBs detected at concentrations above screening levels:

RBC – Aroclor 1254;
SSL – none; and
Eco – none.

TCL VOCs (Method 8260B) – 8 VOCs were detected in soil samples with the following VOCs detected at concentrations above screening levels:

RBC – none;
SSL – TCE; and
Eco – none.

TCL SVOCs/PAHs– 15 SVOCs/PAHs were detected in soil samples with the following SVOCs/PAHs detected at concentrations above screening levels:

RBC – none;
SSL – none; and
Eco – none.

Explosives (Method 8330) and Nitroglycerin (Method 8332) – 2 explosives were detected in soil samples with the following constituents detected at concentrations above screening levels:

RBC – none;
SSL – 2,4-DNT; and
Eco – none.

4.3.2 Human Health Nature and Extent Assessment

A summary of the human health risk and background screening results for COPCs is presented in the table below.

Summary of COPCs for Soil

Chemical	Total # of Det/ # of Samples	Above Adjusted R-RBC		Above Adjusted I-RBC	
		# Above	Sample IDs	# Above	Sample IDs
Aluminum*	24/24	0	NA	0	NA
Chromium	24/24	6	37SB1A, 37SB2A, 37SB7A, 37SB8A DUP AVG, 37SB9A DUP AVG, 37SB10A	0	NA
Mercury	18/24	2	37SB7A, 37SB10A	0	NA
Aroclor 1254	8/16	5	37SB1A, 37SB7A, 37SB8A DUP AVG, 37SB9A DUP AVG, 37SB10A	0	NA

Notes: NA=Not Applicable, DUP AVG = Duplicate Average, *No sample concentrations were above the background point estimate for aluminum but aluminum was identified as a hazard driver in human health risk assessment

The nature and extent of COPCs identified in the above table, as well as constituents with concentrations above SSL DAF20s (above background concentrations for inorganics) identified in Section 4.3.1 and presented on Table 4-6, is discussed further in the following sections.

4.3.2.1 Aluminum

Aluminum was detected at concentrations above its R-RBC but below its background point estimate and adjusted I-RBC in all samples collected. Although aluminum was not detected at concentrations above its background point estimate, it was identified as a hazard driver for the construction worker in the HHRA; therefore, aluminum is included in the nature and extent assessment for the site (Figure 4-4). Detected aluminum concentrations within the drying bed (13,100 to 29,000 mg/kg) were similar to detected aluminum concentrations outside the drying bed (9,400 to 20,000 mg/kg) where no indications of impacts from site use were noted (i.e., no sludge present). The detected concentrations also were within the mid-range of detected concentrations of aluminum in the background data set (3,620 to 47,900 mg/kg). An SSL DAF20 is not available for aluminum, but the groundwater sample results did not indicate the leaching of aluminum from soil to groundwater at concentrations above its adjusted T-RBC.

4.3.2.2 Chromium

Chromium was detected at concentrations above its R-RBC and background point estimate in six surface soil/sludge samples collected within the drying bed. Detected concentrations in these samples were below the adjusted I-RBC. Detected chromium concentrations in samples collected from 1 foot below the sludge to the boring termination depths were below the R-RBC and background point estimate indicating the vertical extent of concentrations above the adjusted R-RBC and background point estimate is limited to the sludge material and depths less than 6 ft bgs (Figure 4-4). Although 6 surface soil/sludge samples collected within the drying bed were above chromium's SSL DAF20, subsurface soil sample results did not indicate leaching of chromium from the sludge to underlying soil at levels above the SSL DAF20 or the background point estimate (Figure 4-5). In addition, groundwater sample results did not indicate the leaching of chromium from soil to groundwater at concentrations above its adjusted T-RBC.

4.3.2.3 Mercury

Mercury was detected at concentrations above its R-RBC and background point estimate in two surface soil/sludge samples collected within the drying bed. Detected concentrations in these samples were below its adjusted I-RBC. Detected mercury concentrations in samples collected from 1 foot below the sludge to the boring termination depths were below the R-RBC and background point estimate indicating the vertical extent of concentrations above the adjusted R-RBC and background point estimate is limited to the sludge material and depths less than 6 ft bgs (Figure 4-4). An SSL DAF20 is not available for mercury, but the groundwater sample results did not indicate the leaching of mercury from soil to groundwater at detectable concentrations.

4.3.2.4 Pesticides

Pesticides were detected in samples at concentrations below their adjusted RBCs. One pesticide, dieldrin, was detected in one surface soil/sludge sample (37SB1A) at a concentration above its SSL DAF20. Although one surface soil/sludge sample was above dieldrin's SSL DAF20, soil sample results did not indicate leaching of dieldrin to subsurface soil below the sludge (Figure 4-5). In addition, groundwater sample results did not indicate the leaching of dieldrin from soil to groundwater at detectable concentrations. Additional discussion and assessment of the soil-to-groundwater migration pathway is presented in Section 4.3.3.

4.3.2.5 PCBs

Aroclor 1254 was detected at concentrations above its adjusted R-RBC in 5 of 16 soil samples. The sample concentrations above its adjusted R-RBC are limited to surface soil/sludge samples collected within the drying bed (Figure 4-4). Detected concentrations were below its adjusted I-RBC and SSL DAF20. Detected Aroclor 1254 concentrations in samples collected from 1 foot below the sludge to the boring termination depths were below the R-RBC indicating the vertical extent of concentrations above the adjusted R-RBC is limited to the sludge material and depths less than 6 ft bgs (Figure 4-4).

Groundwater sample results did not indicate leaching of PCBs from soil to groundwater at detectable levels.

4.3.2.6 VOCs

VOCs were detected in samples at concentrations below their adjusted RBCs and SSL DAF20s with the exception of TCE, which detected at concentrations above its SSL DAF20 in two samples. Although TCE was detected in two samples at concentrations above its SSL DAF20, groundwater sample results did not indicate leaching of TCE from soil to groundwater at detectable levels. Additional discussion and assessment of the soil-to-groundwater migration pathway is presented in Section 4.3.3.

4.3.2.7 SVOCs

SVOCs were detected in samples at concentrations below their adjusted RBCs and SSL DAF20s.

4.3.2.8 Explosives

Explosives were detected in samples at concentrations below their adjusted RBCs. One explosive, 2,4-DNT, was detected in one surface soil/sludge sample (37SB2A) at a concentration above its SSL DAF20. Although one surface soil/sludge sample was above 2,4-DNT's SSL DAF20, soil sample results did not indicate leaching of 2,4-DNT to subsurface soil below the sludge (Figure 4-5). In addition, groundwater sample results did not indicate the leaching of 2,4-DNT from soil to groundwater at detectable concentrations. Additional discussion and assessment of the soil-to-groundwater migration pathway is presented in Section 4.3.3.

4.3.3 Soil-to-groundwater Migration Assessment

As previously discussed in Section 4.3.1 and presented on Table 4-6, the concentrations for each detected chemical at the site was screened against the SSL DAF20 and background point estimate resulting in the identification of the following SSL COPCs: chromium, dieldrin, TCE, and 2,4-DNT. Sample concentrations that were above SSL DAF20s and background point estimates (inorganics only) are summarized in the table below:

Chemical	Total # of Det/# of Samples	# of Samples Above SSL DAF20	Sample Identification
Chromium	24/24	6	37SB1A, 37SB2A, 37SB7A, 37SB8A DUP AVG, 37SB9A DUP AVG, 37SB10A
Dieldrin	1/16	1	37SB1A
TCE	2/9	2	37SB2B, 37SB2C
2,4-DNT	3/24	1	37SB2A

Although chromium was detected at a concentration in one or more samples at above its SSL DAF20 and background point estimate (Figure 4-5), dissolved chromium was not detected in groundwater samples at levels above its adjusted T-RBC or MCL.

While SSL exceedances indicate a theoretical potential for impact to groundwater, empirical evidence in the form of actual groundwater chemical data, soil boring characterization and chemical analyses, soil characteristics/chemistry, and fate and transport analysis offer more concrete evidence of site conditions and potential impact to groundwater. Given the age of the sludge in the drying bed (>20 years), the organic content within the sludge, limited organic detections above the SSLs, the lack of detections in groundwater for dieldrin, TCE, and 2,4,-DNT, and the lack of detections in groundwater of chromium at concentrations above its adjusted T-RBC, these chemicals are not a concern at the site with respect to

migration from soil to groundwater. Additional fate and transport information for these chemicals is provided in Section 5.1.4.

4.3.4 Ecological Nature and Extent Assessment

As presented in Section 7.3.3, after consideration of the results of the SLERA, site conditions, background concentrations, and nature of the material in place at the site, the SMDP is the following:

There is adequate information to conclude that ecological risks are negligible and therefore there is no need for further action at the site on the basis of ecological risk.

4.4 NATURE AND EXTENT – SWMU 37 GROUNDWATER

4.4.1 Monitoring Well Analytical Results

Monitoring well sample results from wells 37MW1, 37MW2, 37MW3, and 37MW4 are summarized in Table 4-7. Table 4-8 summarizes the screening results for groundwater data including: constituents detected, minimum and maximum concentrations detected, number of detections, number of samples, and number of samples above human health screening criteria. Note: Table 4-8 screens the pesticide data from the June 2007 sampling event for 37MW2. The screening resulted in the identification of the following COPCs:

TAL Metals (Methods 6010B, 6020A, 7470A) – 18 TAL metals were detected in groundwater at concentrations below their adjusted T-RBCs with the exception of aluminum (total), arsenic (total), barium, (total), iron (total), vanadium (total), and manganese (total and dissolved).

TCL Pesticides (Method 8081A) – 8 pesticides were detected in groundwater at concentrations below their adjusted T-RBCs with the exception of alpha-BHC, alpha-chlordane, beta-BHC, delta-BHC, and heptachlor epoxide. Heptachlor epoxide and alpha-chlordane were below their MCLs.

TCL PCBs (Method 8082) – PCBs were not detected in groundwater.

TCL VOCs (Method 8260B) – 4 VOCs were detected in groundwater at concentrations below their adjusted T-RBCs and MCLs with the exception of chloroform which was above its T-RBC but was below the MCL for total THMs.

TCL SVOCs (Method 8270C) – SVOCs were not analyzed for in groundwater.

Explosives (Method 8330) and Nitroglycerin (Method 8332) – 4 explosives were detected in groundwater at a concentrations below their adjusted T-RBC. Nitroglycerin was not detected in groundwater.

Perchlorate (Method 6850) – Perchlorate was detected in groundwater at concentrations below its adjusted T-RBC.

4.4.2 Human Health Nature and Extent Assessment

The groundwater risk screening identified manganese, pesticides, and chloroform as COPCs for groundwater. Note that 37MW2 was re-sampled and tested for pesticides in June 2008. The nature and extent of these COPCs in groundwater is discussed below and presented on Figure 4-6:

Manganese

As shown on Figure 4-6, dissolved manganese was detected at a concentration above its adjusted T-RBC of 73 µg/L in the sample collected from well 37MW2 (260 µg/L). Detected concentrations were below the unadjusted T-RBC of 730 µg/L.

Pesticides

For the February 2008 sampling event (Figure 4-6), alpha-BHC, beta-BHC, and delta-BHC were detected in well 37MW2 at concentrations above their adjusted T-RBCs. During this same sampling event

(February 2008), alpha-chlordane and heptachlor epoxide were detected in background well 37MW1 at concentrations above their adjusted T-RBCs but below their MCLs. Groundwater from downgradient well 37MW2 was re-sampled and analyzed for pesticides in June 2008, which resulted in detected concentrations of alpha-BHC and heptachlor epoxide above their adjusted T-RBCs (Figure 4-6). The detected heptachlor epoxide concentration was below its MCL. An MCL is not available for alpha-BHC, but as presented in Section 6.0, alpha-BHC was not identified as a risk or hazard driver in the human health risk assessment.

Chloroform

Chloroform was detected at a concentration above its T-RBC of 0.155 µg/L in the sample collected from well 37MW3 (0.28 µg/L). The detected concentration was below the MCL of 80 µg/L for chloroform (total THMs).

4.5 NATURE AND EXTENT – SWMU 38/AOC Q SOIL

4.5.1 Analytical Results

Thirteen surface soil samples and 20 subsurface soil samples for a total of 33 samples were collected for chemical analysis from SWMU 38/AOC Q (Figure 3-3 and Table 3-1). Soil samples for chemical analysis were collected from borings from up to three intervals including: a surface soil sample ("A" sample), immediately below sludge (if present) or intermediate sample ("B" sample), and a terminal depth sample ("C" sample). Table 4-9 presents analytical results for chemicals detected in soil samples collected at SWMU 38/AOC Q and screens these data with respect to adjusted RBCs, SSLs, and background concentrations. Table 4-10 summarizes the screening results for soil data including: constituents detected, minimum and maximum concentrations detected, number of detections, number of samples, and the number of samples above human health screening criteria or SSL DAF20 screening levels and background concentrations (inorganics only). COPECs listed below were identified for the site as part of the refined screening level ecological risk assessment presented in Section 7.4.3 and above background point estimates (inorganics only). The screenings resulted in the identification of the following COPCs and COPECs (note that chemicals which were below background point estimates but were identified as hazard drivers for the HHRA are italicized):

TAL Metals (Methods 6010B, 6020A, 7471A) – 23 TAL metals were detected in soil samples with the following metals detected at concentrations above screening levels:

RBC – *aluminum*, chromium, *manganese*;
SSL – chromium; and
Eco – calcium.

TCL Pesticides (Method 8081A) – 2 pesticides were detected in soil samples with the following pesticides detected at concentrations above screening levels:

RBC – none;
SSL – none; and
Eco – none.

TCL PCBs (Method 8082) – 1 PCB was detected in soil samples with the following PCB detected at concentrations above screening levels:

RBC – Aroclor 1254;
SSL – none; and
Eco – none.

TCL VOCs (Method 8260B) – 9 VOCs were detected in soil samples with the following VOCs detected at concentrations above screening levels:

RBC – none;
SSL – none; and
Eco – none.

TCL SVOCs (Method 8270C) – 12 SVOCs were detected in soil samples with the following SVOCs detected at concentrations above screening levels:

RBC – none;
SSL – none; and
Eco – none.

Explosives (Method 8330) and Nitroglycerin (Method 8332) – 1 explosive was detected in soil samples with the following constituents detected at concentrations above screening levels:

RBC –none;
SSL – none; and
Eco – none.

4.5.2 Human Health Nature and Extent Assessment

A summary of the human health risk and background screening results for COPCs is presented in the table below.

Summary of COPCs for Soil

Chemical	Total # of Det/ # of Samples	Above Adjusted R-RBC		Above Adjusted I-RBC	
		# Above	Sample IDs	# of Above	Sample IDs
Aluminum*	33/33	0	NA	0	NA
Chromium	33/33	3	38SB1A, 38SB3A, 38B10A	0	NA
Manganese*	33/33	0	NA	0	NA
Aroclor 1254	9/18	3	38SB1A, 38SB7A DUP AVG, QSB4A	0	NA

Notes: NA=Not Applicable, DUP AVG = Duplicate Average, *No sample concentrations were above the background point estimate for aluminum and manganese, but aluminum and manganese were identified as a hazard driver in human health risk assessment

The nature and extent of COPCs identified in the above table, as well as constituents with concentrations above SSL DAF20s (above background concentrations for inorganics) identified in Section 4.5.1 and presented on Table 4-10, is discussed further in the following sections.

4.5.2.1 Aluminum

Aluminum was detected at concentrations above its R-RBC but below its background point estimate and adjusted I-RBC in all samples collected. Although aluminum was not detected at concentrations above its background point estimate, it was identified as a hazard driver for the construction worker in the HHRA; therefore, aluminum is included in the nature and extent assessment for the site (Figure 4-7). Detected aluminum concentrations within the drying bed (3,360 to 26,400 mg/kg) were similar to detected aluminum concentrations outside the drying bed (7,820 to 18,150 mg/kg) where no indication of impacts from site use were noted (i.e., no sludge present). The detected concentrations also were within the mid-range of detected concentrations of aluminum in the background data set (3,620 to 47,900 mg/kg). An SSL DAF20 is not available for aluminum, but the groundwater sample results did not indicate the leaching of aluminum from soil to groundwater at concentrations above its adjusted T-RBC.

4.5.2.2 Chromium

Chromium was detected at concentrations above its R-RBC and background point estimate in 3 surface soil/sludge samples collected within the drying bed. Detected concentrations in these samples were below its adjusted I-RBC. Detected chromium concentrations in samples collected from 1 foot below the sludge to the boring termination depths were below the R-RBC and background point estimate indicating the vertical extent of concentrations above the adjusted R-RBC and background point estimate is limited to the sludge material and a maximum depth of 1 ft bgs (Figure 4-7). Although 3 surface soil/sludge

samples were above chromium's SSL DAF20, subsurface soil sample results did not indicate leaching of chromium from the sludge to underlying soil at levels above the SSL DAF20 or the background point estimate (Figure 4-8). In addition, groundwater sample results did not indicate the leaching of chromium from soil to groundwater at concentrations above its adjusted T-RBC.

4.5.2.3 Manganese

Manganese was detected at concentrations above its R-RBC but below its background point estimate and adjusted I-RBC in all samples collected. Although manganese was not detected at concentrations above its background point estimate, it was identified as a hazard driver for the construction worker in the HHRA; therefore, manganese is included in the nature and extent assessment for the site (Figure 4-7). Detected manganese concentrations within the drying bed (87 to 550 mg/kg) were similar to detected manganese concentrations outside the drying bed (222 to 600 mg/kg) where no indication of impacts from site use were noted (i.e., no sludge present). The detected concentrations also were within the low-to-mid range of detected concentrations of manganese in the background data set (16.7 to 2,040 mg/kg). Although detected manganese concentrations in soil were not above its SSL DAF20, the groundwater sample results resulted in manganese concentrations in groundwater above its adjusted and unadjusted T-RBC at one well location (38MW3).

4.5.2.4 Pesticides

Pesticides were detected in samples at concentrations below their adjusted RBCs and SSL DAF20s.

4.5.2.5 PCBs

Aroclor 1254 was detected at concentrations above its adjusted R-RBC in 3 of 18 soil samples but below its I-RBC. The sample concentrations above its adjusted R-RBC are limited to surface soil/sludge within the drying bed. The vertical extent of detected concentrations of PCBs above adjusted R-RBC is limited to surface soil/sludge within the drying bed and to a maximum depth of 1 ft bgs (Figure 4-7). PCBs were not detected in soil at concentrations above SSL DAF20s and the groundwater sample results did not indicate leaching of PCBs from soil to groundwater at detectable levels.

4.5.2.6 VOCs

VOCs were detected in samples at concentrations below their adjusted RBCs and SSL DAF20s.

4.5.2.7 SVOCs

SVOCs were detected in samples at concentrations below their adjusted RBCs and SSL DAF20s.

4.5.2.8 Explosives

Explosives were detected in samples at concentrations below their adjusted RBCs and SSL DAF20s.

4.5.3 Soil-to-groundwater Migration Assessment

As previously discussed in Section 4.5.1 and presented on Table 4-10, the concentrations for each detected chemical at the site was screened against the DAF20 SSL and background point estimate resulting in the identification of the following SSL COPC: chromium. Sample concentrations that were above the SSL DAF20 and background point estimate are summarized in the table below:

Chemical	Total # of Det/# of Samples	# of Samples Above SSL DAF20	Sample Identification
Chromium	33/33	3	38SB1A, 38SB3A, 38B10A

Although chromium was detected at a concentration in one or more samples above its DAF20 SSL and background point estimate, chromium was not detected in subsurface soil samples collected below the

sludge at concentrations above these levels (Figure 4-8). In addition, chromium was not detected in groundwater samples at levels above its adjusted T-RBCs.

While SSL exceedances indicate a theoretical potential for impact to groundwater, empirical evidence in the form of actual groundwater chemical data, soil boring characterization and chemical analyses, soil characteristics/chemistry, and fate and transport analysis offer more concrete evidence of site conditions and potential impact to groundwater. Given the age of the sludge in the drying bed (>20 years), the organic content within the sludge, limited detections above the SSL, and the lack of detections in groundwater of chromium at concentrations above its adjusted T-RBC, this chemical is not a concern at the site with respect to migration from soil to groundwater. Additional fate and transport information for chromium is provided in Section 5.1.4.

4.5.4 Ecological Nature and Extent Assessment

As presented in Section 7.4.3, after consideration of the results of the SLERA, background concentrations, site conditions, and nature of the material in place at the site, the SMDP is the following:

There is adequate information to conclude that ecological risks are negligible and therefore there is no need for further action at the site on the basis of ecological risk.

4.6 NATURE AND EXTENT – SWMU 38/AOC Q GROUNDWATER

4.6.1 Monitoring Well Analytical Results

Monitoring well sample results from wells 38MW1, 38MW2, and 38MW3, are summarized in Table 4-11. Table 4-12 summarizes the screening results for groundwater data including: constituents detected, minimum and maximum concentrations detected, number of detections, number of samples, and the number of samples above human health screening criteria. The screening resulted in the identification of the following COPCs:

TAL Metals (Methods 6010B, 6020A, 7470A) – 17 TAL metals were detected in groundwater at concentrations below their adjusted T-RBCs with the exception of arsenic (total), iron (total), manganese (total and dissolved), and vanadium (total).

TCL Pesticides (Method 8081A) – 2 pesticides were detected in groundwater at concentrations below their adjusted T-RBCs.

TCL PCBs (Method 8082) – PCBs were not detected in groundwater.

TCL VOCs (Method 8260B) – 3 VOCs were detected in groundwater at concentrations below their adjusted T-RBCs and MCLs with the exception of chloroform, which is above its T-RBC but was below the MCL for THMs.

TCL SVOCs (Method 8270C) – SVOCs were not analyzed for in groundwater.

Explosives (Method 8330) and Nitroglycerin (Method 8332) – Explosives were not detected in groundwater.

Perchlorate (Method 6850) – Perchlorate was detected in groundwater at a concentration below its adjusted T-RBC.

4.6.2 Human Health Nature and Extent Assessment

The groundwater risk screening identified dissolved manganese and chloroform as COPCs for groundwater. The nature and extent of these COPCs in groundwater is discussed below and presented on Figure 4-9:

Manganese

For the February 2008 sampling event (Figure 4-9), dissolved manganese was detected at a concentration above its adjusted and unadjusted T-RBC of 73 µg/L in the sample collected from well 38MW3 (2,400 µg/L). Groundwater from downgradient well 38MW3 was re-sampled and analyzed for manganese in June 2008. The dissolved manganese concentration detected (1,050 µg/L) is also above its adjusted and unadjusted T-RBC (Figure 4-9).

Chloroform

As presented on Figure 4-9, chloroform was detected at a concentration above its T-RBC of 0.155 µg/L in the sample collected from well 38MW1 (1.7 µg/L). Detected concentrations were below the MCL of 80 µg/L for chloroform (total THMs).

4.7 NATURE AND EXTENT SUMMARY

4.7.1 Nature and Extent Summary – SWMU 35

The primary site-related COPCs in soil at SWMU 35 are metals, PCBs, and nitroglycerin located primarily within the drying bed. These conclusions are supported by the results of the human health and ecological risks assessments presented in Sections 6.0 and 7.0, respectively. Metals concentrations in soil were highest within sludge contained in the drying bed (Figure 4-1). Aroclor 1254 concentrations above its adjusted I-RBCs were limited to one surface soil/sludge sample collected within the drying bed (Figure 4-1).

As shown on Figure 4-2, sample concentrations above its SSL DAF20 and background point estimate for chromium were limited to surface soil/sludge samples collected within the drying bed. Chromium was not detected in groundwater at concentrations above its adjusted T-RBC. Given the age of the sludge in the drying bed (>20 years), the high organic content within the sludge, limited detections above the SSL, no detections in the subsurface soil above SSLs, the lack of detections in groundwater for Aroclor 1254, and the lack of detections in groundwater of chromium at concentrations above its adjusted T-RBC, these chemicals are not a concern at the site with respect to migration from soil to groundwater.

The results of the ecological risk assessment indicated that there is adequate information to conclude that ecological risks are negligible and therefore there is no need for further action at the site on the basis of ecological risk.

COPCs identified in groundwater were limited to manganese and chloroform, with dissolved metals and chloroform concentrations detected below their unadjusted T-RBCs or MCLs (Figure 4-3). It is important to note that studies and groundwater investigations have shown the presence of chloroform in most groundwater samples collected at the facility regardless of location. The concentrations of chloroform detected in monitoring wells at SWMU 35 are low level concentrations below the range of chloroform levels present in the water transmitted through water lines at the facility. The site is located downgradient of developed areas containing water lines that could be leaking, which may have been the source of chloroform. In addition, as presented in Section 6.0 chloroform was not identified as a risk driver in the human health risk assessment.

COPCs identified in the nature and extent assessment are summarized in the following table.

Summary of Nature and Extent Assessment – SWMU 35

Chemical	HH Soil COPC [1]	HH Groundwater COPC [1]
Aluminum	X	
Calcium		
Chromium	X	
Lead	X	
Manganese		X
Mercury		
Aroclor 1254	X	
Aroclor 1260	X	
Chloroform		X
Nitroglycerin	X	

Note: [1] Chemicals with available screening values

4.7.2 Nature and Extent Summary – SWMU 37

The primary site-related COPCs in soil at SWMU 37 are metals and PCBs located within the drying bed. These conclusions are supported by the results of the human health and ecological risks assessments presented in Sections 6.0 and 7.0, respectively. Metals concentrations in soil were highest within sludge contained in the drying bed (Figure 4-4). Aroclor 1254 concentrations above its adjusted R-RBC were limited to surface soil/sludge sample collected within the drying bed (Figure 4-4).

As shown on Figure 4-5, sample concentrations of chromium above its SSL DAF20 and background point estimate were limited to surface soil/sludge samples collected within the drying bed. Chromium was not detected in groundwater at concentrations above its adjusted T-RBC. Given the age of the sludge in the drying bed (>20 years), the organic content within the sludge, limited organic detections above the SSLs, the lack of detections in groundwater for dieldrin, TCE, and 2,4,-DNT, and the lack of detections in groundwater of chromium at concentrations above its adjusted T-RBC, these chemicals are not a concern at the site with respect to migration from soil to groundwater.

The results of the ecological risk assessment indicated that there is adequate information to conclude that ecological risks are negligible and therefore there is no need for further action at the site on the basis of ecological risk.

COPCs identified in groundwater were limited to manganese, pesticides (alpha-BHC and heptachlor epoxide), and chloroform, with dissolved metals, heptachlor epoxide, and chloroform concentrations detected below their unadjusted T-RBCs or MCLs (Figure 4-6). An MCL is not available for alpha-BHC, but as presented in Section 6.0, alpha-BHC was not identified as a risk or hazard driver in the human health risk assessment.

It is important to note that studies and groundwater investigations have shown the presence of chloroform in most groundwater samples collected at the facility regardless of location. The concentrations of chloroform detected in monitoring wells at SWMU 37 are low level concentrations below the range of chloroform levels present in the water transmitted through water lines at the facility. The site is located downgradient of developed areas containing water lines that could be leaking, which may have been the source of chloroform. In addition, as presented in Section 6.0 chloroform was not identified as a risk driver in the human health risk assessment. Data suggests the site is not the source of pesticides in groundwater since the pesticides detected in groundwater were not detected in soil at the site and pesticides were also detected in background well 37MW1.

COPCs identified in the nature and extent assessment are summarized in the following table.

Summary of Nature and Extent Assessment – SWMU 37

Chemical	HH COPC[1]	Groundwater COPC [1,2]
Aluminum	X	
Calcium		
Chromium	X	
Copper		
Manganese		X
Mercury	X	
Aroclor 1254	X	
Dieldrin		
alpha-BHC[2]		X
Heptachlor Epoxide[2]		X
Chloroform		X
TCE		
2,4-DNT		

Note: [1] Chemicals with available screening values
[2] Groundwater COPCs for downgradient wells – June 2008 sampling event

4.7.3 Nature and Extent Summary – SWMU 38 and AOC Q

The primary site-related COPCs in soil at SWMU 38/AOC Q are metals and Aroclor 1254 located within the drying bed. These conclusions are supported by the results of the human health and ecological risks assessments presented in Sections 6.0 and 7.0, respectively. Metals concentrations in soil were highest in sludge contained in the drying bed (Figure 4-7). Aroclor 1254 concentrations above its adjusted R-RBC were limited to surface soil/sludge samples collected within the drying bed (Figure 4-7).

As shown on Figure 4-8, sample chromium concentrations above its SSL DAF20 and background point estimate were limited to surface soil/sludge samples collected within the drying bed. Although chromium was detected in soil within the surface soil/sludge in the drying bed at concentrations above its site-specific SSL, chromium was not detected in groundwater at concentrations above its adjusted T-RBC.

The results of the ecological risk assessment indicated that there is adequate information to conclude that ecological risks are negligible and therefore there is no need for further action at the site on the basis of ecological risk.

COPCs identified in groundwater were limited to manganese and chloroform, with chloroform concentrations detected below its MCLs (Figure 4-9). It is important to note that studies and groundwater investigations have shown the presence of chloroform in most groundwater samples collected at the facility regardless of location. The concentrations of chloroform detected in monitoring wells at SWMU 38/AOC Q are low level concentrations below the range of chloroform levels present in the water transmitted through water lines at the facility. The site is located downgradient of developed areas containing water lines that could be leaking, which may have been the source of chloroform. In addition, as presented in Section 6.0 chloroform was not identified as a risk driver in the human health risk assessment.

A site-specific source related to disposal activities for the dissolved manganese concentrations detected in well 38MW3 was not identified. Manganese concentrations within material in the drying bed (87 to 550 mg/kg) were similar to manganese concentrations in soil outside the drying bed (222 to 600 mg/kg) where no indication of impacts from site use were noted (i.e., no sludge present). Manganese concentrations at the site also were within the low-to-mid range of concentrations of manganese in the background data set (16.7 to 2,040 mg/kg). The occurrence of dissolved manganese at concentrations above the T-RBC at one well location 38MW3 may be due natural geologic conditions (i.e., weathering of bedrock containing

manganese and alluvial deposition). COPCs identified in the nature and extent assessment are summarized in the following table.

Summary of Nature and Extent Assessment – SWMU 38 and AOC Q

Chemical	HH COPC[1]	Groundwater COPC[1]
Aluminum	X	
Calcium		
Chromium	X	
Manganese	X	X
Aroclor 1254	X	
Chloroform		X

Note: [1] Chemicals with available screening values

Notes:

CAS = Chemical Abstracts Service
ft bgs = Feet Below Ground Surface
mg/kg = Milligram Per Kilogram
µg/kg = Microgram Per Kilogram
TAL = Target Analyte List
TCL = Target Compound List
PCB = Polychlorinated Biphenyl
VOC = Volatile Organic Compound
SVOC = Semi-volatile Organic Compound
MDL = Method Detection Limit
RL = Reporting Limit
LQ = Laboratory Qualifier
VQ = Validation Qualifier
r = Reason Code
NT = Not Tested
ND = Not Detected
-- = No Value Available

[A] = Facility Background = Facility-Wide Background Point Estimate as Reported in the Facility-Wide Background Study Report (IT 2001)
RBC = USEPA Region III Risk-Based Concentration (RBC) values from the October 11, 2007, RBC Table and October 11, 2007, Alternate RBC Table
Adjusted RBCs = a Hazard Quotient (HQ) of 0.1 applied to non-carcinogens
C/N = Carcinogenic/Noncarcinogenic per EPA RBC Table (October 2007)
SSL DAF20 = Soil Screening Level at a Dilution Attenuation Factor of 20
[1] = Chromium VI RBC value was used
[2] = Lead criteria are Action Levels; see USEPA Region III guidance
[3] = Mercuric chloride soil RBC value used
[4] = Noncarcinogenic Residential RBC value for Aroclor 1254 was used for screening
[5] = Noncarcinogenic Residential and Industrial RBC values for 2,4,6-Trinitrotoluene were used for screening

= Concentration Exceeds Adjusted Soil Residential RBC

= Concentration Exceeds Adjusted Soil Industrial RBC

underline = Concentration Exceeds Site Background Values

bold italic = Concentration Exceeds SSL DAF20

Laboratory Qualifiers

B	Analyte found in associated blank as well as in the sample.
J	Estimated value.
U	The compound was analyzed for but not detected. The reporting limit will be adjusted to reflect any dilution, and for soil, the percent moisture.

Validation Qualifiers

B	Not detected substantially above the level reported in laboratory or field blanks.
K	Analyte present. Reported value may be biased high. Actual value is expected to be lower.
N	Tentative Identification. Consider present. Special methods may be needed to confirm its presence or absence in future sampling efforts.
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
L	Analyte present. Reported value may be biased low. Actual value is expected to be higher.
U	Not detected. The associated number indicates the approximate sample concentration necessary to be detected.
UJ	Not detected, quantitation limit may be inaccurate or imprecise.
UL	Not detected, quantitation limit is probably higher.

Reason Codes

GC/MS Organics

c	Calibration failure; poor (RRF) or unstable (%D) response
f	Field duplicate imprecision
l	MS/MSD recovery failure
s	Surrogate failure
t	Tentatively identified compound
x	Field and/or equipment blank contamination
z	Method blank and/or storage blank contamination

GC and HPLC Organics

c	Calibration failure; poor or unstable (%D) response
f	Field duplicate imprecision
g	Dual column confirmation imprecision
l	MS/MSD recovery failure
s	No confirmation column
x	Trip blank contamination
z	Method blank and/or storage blank contamination

Inorganics and Conventionals

f	Field duplicate imprecision
m	MS/MSD recovery failure
p	Preparation blank contamination
s	Serial dilution failure

Table 4-2
Summary of Risk Screening Results for Soil - SWMU 35
SWMUs 35, 37, 38, and AOC Q RFI Report
Radford Army Ammunition Plant, Radford, Virginia

Notes:

CAS = Chemical Abstract Service
mg/kg = Milligram per Kilogram
µg/kg = Microgram per kilogram
TAL = Target Analyte List
TCL = Target Compound List
PCB = Polychlorinated Biphenyl
VOC = Volatile Organic Compound
SVOC = Semivolatile Organic Compound
Facility Background = Facility-Wide Background Point Estimate as Reported in the Facility-Wide Background Study Report (IT 2001)
RBC = USEPA Region III Risk-Based Concentration
(RBC) values from the October 11, 2007,
RBC Table and October 11, 2007, Alternate RBC Table
Adjusted RBCs = a Hazard Quotient (HQ) of 0.1 applied to non-carcinogens
R-RBC = Adjusted Residential RBC
I-RBC = Adjusted Industrial RBC
C = Carcinogenic per EPA RBC Table (October 2007)
N = Noncarcinogenic per EPA RBC Table (October 2007)
SSL DAF20 = Soil Screening Level at a Dilution Attenuation Factor of 20
-- = No screening value available

[A] = For inorganics, number of samples that exceed background (if available) and screening level
[1] = Chromium VI RBC value was used
[2] = Lead criteria are Action Levels; see USEPA Region III guidance
[3] = Mercuric chloride soil RBC value used
[4] = Noncarcinogenic Residential RBC value for Aroclor 1254 was used for screening
[5] = Noncarcinogenic Residential and Industrial RBC values for 2,4,6-Trinitrotoluene were used for screening

Notes:
CAS = Chemical Abstracts Service
µg/L = Microgram Per Liter
TAL = Target Analyte List
TCL = Target Compound List
SVOC = Semi-volatile Organic Compound
MDL = Method Detection Limit
RL = Reporting Limit
LQ = Laboratory Qualifier
VQ = Validation Qualifier
r = Reason Code
NT = Not Tested
mg/L = Milligram Per Liter
mV = millivolt
SU = Standard Units
mS = milliSiemen
°C = degrees Celcius
ntu = Nephelometric Turbidity
NR = Not Recorded (Equipment Not Functioning Properly)
RBC = USEPA Region III Risk-Based Concentration (RBC) values from the October 11, 2007, RBC Table and October 11, 2007, Alternate RBC Table
C = Carcinogenic per EPA RBC Table (October 2007)
N = Noncarcinogenic per EPA RBC Table (October 2007)
MCL = Maximum Contaminant Level
-- = No Value Available

[1] = Chromium VI RBC used for screening
[2] = USEPA Action Level used for screening
[3] = Chlordane RBC used for screening
[4] = Pyrene RBC used for screening

=Exceeds MCL

=Exceeds Adjusted T-RBC

Data Qualifiers:
B = Not detected substantially above the level reported in laboratory or field blanks.
J = Analyte present. Reported value may not be accurate or precise.
L = Analyte present. Reported value may be biased low. Actual value is expected to be higher.
U = Not detected. The associated number indicates the approximate sample concentration necessary to be detected.
f = Field duplicate imprecision
m = MS/MSD recovery failure.
o = Calibration blank contamination
p = Preparation blank contamination
x = Trip blank contamination
y = Trip blank contamination
z = Method blank and/or storage blank contamination

Notes:

CAS = Chemical Abstracts Service
ft bgs = Feet Below Ground Surface
mg/kg = Milligram Per Kilogram
µg/kg = Microgram Per Kilogram
TAL = Target Analyte List
TCL = Target Compound List
PCB = Polychlorinated Biphenyl
VOC = Volatile Organic Compound
SVOC = Semi-volatile Organic Compound
PAH = Polynuclear Aromatic Hydrocarbon
MDL = Method Detection Limit
RL = Reporting Limit
LQ = Laboratory Qualifier
VQ = Validation Qualifier
r = Reason Code
NT = Not Tested
NR = Not Reported
NI = Not Identified
-- = No Value Available

[A] = Facility Background = Facility-Wide Background Point Estimate as Reported in the Facility-Wide Background Study Report (IT 2001)
RBC = USEPA Region III Risk-Based Concentration (RBC) values from the October 11, 2007, RBC Table and October 11, 2007, Alternate RBC Table
Adjusted RBCs = a Hazard Quotient (HQ) of 0.1 applied to non-carcinogens
C/N = Carcinogenic/Noncarcinogenic per EPA RBC Table (October 2007)
SSL DAF20 = Soil Screening Level at a Dilution Attenuation Factor of 20
[1] = Chromium VI RBC value was used
[2] = Lead criteria are Action Levels; see USEPA Region III guidance
[3] = Mercuric chloride soil RBC value used
[4] = Noncarcinogenic Residential RBC value for Aroclor 1254 was used for screening
[5] = 3-Methylphenol RBC value was used
[6] = Pyrene RBC value was used

= Concentration Exceeds Adjusted Soil Residential RBC

= Concentration Exceeds Adjusted Soil Industrial RBC

underline = Concentration Exceeds Site Background Values

bold italic = Concentration Exceeds SSL DAF20

Laboratory Qualifiers

B	Analyte found in associated blank as well as in the sample.
E	Concentration exceeded the upper level of the calibration range of the instrument for that specific analysis. For TICs, compound not present in calibration standard, calculated using total peak areas ion chromatographs and response factor of
J	Estimated value.
U	The compound was analyzed for but not detected. The reporting limit will be adjusted to reflect any dilution, and for soil, the percent moisture.

Validation Qualifiers

B	Not detected substantially above the level reported in laboratory or field blanks.
K	Analyte present. Reported value may be biased high. Actual value is expected to be lower.
N	Tentative Identification. Consider present. Special methods may be needed to confirm its presence or absence in future sampling efforts.
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
L	Analyte present. Reported value may be biased low. Actual value is expected to be higher.
U	Not detected. The associated number indicates the approximate sample concentration necessary to be detected.
UJ	Not detected, quantitation limit may be inaccurate or imprecise.
UL	Not detected, quantitation limit is probably higher.

Reason Codes

GC/MS Organics

c	Calibration failure; poor (RRF) or unstable (%D) response
f	Field duplicate imprecision
l	MS/MSD recovery failure
s	Surrogate failure
t	Tentatively identified compound
x	Field and/or equipment blank contamination
z	Method blank and/or storage blank contamination

GC and HPLC Organics

c	Calibration failure; poor or unstable (%D) response
f	Field duplicate imprecision
g	Dual column confirmation imprecision
l	MS/MSD recovery failure
s	No confirmation column
x	Trip blank contamination
z	Method blank and/or storage blank contamination

Inorganics and Conventionals

f	Field duplicate imprecision
m	MS/MSD recovery failure
p	Preparation blank contamination
s	Serial dilution failure

Notes:

CAS = Chemical Abstracts Service
µg/L = Microgram Per Liter
TAL = Target Analyte List
TCL = Target Compound List
VOC = Volatile Organic Compound
MDL = Method Detection Limit
RL = Reporting Limit
LQ = Laboratory Qualifier
VQ = Validation Qualifier
r = Reason Code
NT = Not Tested

mg/L = Milligram Per Liter
mV = millivolt
SU = Standard Units
mS = milliSiemen
°C = degrees Celcius
ntu = Nephelometric Turbidity
RBC = USEPA Region III Risk-Based Concentration (RBC) values from the October 11, 2007, RBC Table and October 11, 2007, Alternate RBC Table
C = Carcinogenic per EPA RBC Table (October 2007)
N = Noncarcinogenic per EPA RBC Table (October 2007)
MCL = Maximum Contaminant Level

* Re-sampled 6/24/08 for Pesticides only

[1] = Chromium VI RBC used for screening
[2] = USEPA Action Level used for screening
[3] = Chlordane RBC used for screening
[4] = alpha-BHC RBC used for screening
[5] = Endosulfan RBC used for screening

=Exceeds MCL
=Exceeds Adjusted T-RBC

Data Qualifiers:
B = Not detected substantially above the level reported in laboratory or field blanks.
J = Analyte present. Reported value may not be accurate or precise.
,J = The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
U = Not detected. The associated number indicates the approximate sample concentration necessary to be detected.
UJ = Not detected, quantitation limit may be inaccurate or imprecise.
c = Calibration failure; poor or unstable response
m = MS/MSD recovery failure.
p = Preparation blank contamination
x = Trip blank contamination
z = Method blank and/or storage blank contamination

THIS PAGE LEFT INTENTIONALLY BLANK

Notes:

CAS = Chemical Abstract Service
ug/L = Microgram Per Liter
TAL = Target Analyte List
TCL = Target Compound List
VOC = Volatile Organic Compound
T-RBC = Adjusted Tap Water RBC
RBC = USEPA Region III Risk-Based Concentration
(RBC) values from the October 11, 2007,
RBC Table and October 11, 2007, Alternate RBC Table
Adjusted RBCs = a Hazard Quotient (HQ) of 0.1 applied to non-carcinogens
C/N = Carcinogenic/Noncarcinogenic per EPA RBC Table (October 2007)
MCL = Maximum Contaminant Level
[A] = Pesticide data from the June 2008 groundwater sampling event used in the screening

[1] = Chromium VI RBC value was used
[2] = USEPA Action Level used for screening
[3] = Chlordane RBC used for screening
[4] = alpha-BHC RBC used for screening
[5] = Endosulfan RBC used for screening

Notes:

CAS = Chemical Abstracts Service
ft bgs = Feet Below Ground Surface
mg/kg = Milligram Per Kilogram
µg/kg = Microgram Per Kilogram
TAL = Target Analyte List
TCL = Target Compound List
PCB = Polychlorinated Biphenyl
VOC = Volatile Organic Compound
SVOC = Semi-volatile Organic Compound
PAH = Polynuclear Aromatic Hydrocarbon
MDL = Method Detection Limit
RL = Reporting Limit
LQ = Laboratory Qualifier
VQ = Validation Qualifier
r = Reason Code
NT = Not Tested
NR = Not Reported
NI = Not Identified
-- = No Value Available

[A] = Facility Background = Facility-Wide Background Point Estimate as Reported in the Facility-Wide Background Study Report (IT 2001)
RBC = USEPA Region III Risk-Based Concentration (RBC) values from the October 11, 2007, RBC Table and October 11, 2007, Alternate RBC Table
Adjusted RBCs = a Hazard Quotient (HQ) of 0.1 applied to non-carcinogens
C/N = Carcinogenic/Noncarcinogenic per EPA RBC Table (October 2007)
SSL DAF20 = Soil Screening Level at a Dilution Attenuation Factor of 20
[1] = Chromium VI RBC value was used
[2] = Lead criteria are Action Levels; see USEPA Region III guidance
[3] = Mercuric chloride soil RBC value used
[4] = Endosulfan RBC value was used
[5] = Noncarcinogenic Residential RBC value for Aroclor 1254 was used for screening
[6] = 3-Methylphenol RBC value was used
[7] = Pyrene RBC value was used

= Concentration Exceeds Adjusted Soil Residential RBC

= Concentration Exceeds Adjusted Soil Industrial RBC

underline = Concentration Exceeds Site Background Values

bold italic = Concentration Exceeds SSL DAF20

Laboratory Qualifiers

B	Analyte found in associated blank as well as in the sample.
E	Concentration exceeded the upper level of the calibration range of the instrument for that specific analysis. For TICs, compound not present in calibration standard, calculated using total peak areas ion chromatographs and response factor of
J	Estimated value.
U	The compound was analyzed for but not detected. The reporting limit will be adjusted to reflect any dilution, and for soil, the percent moisture.
Q	Not estimated. TIC detected in sample, quantified using a response factor from the initial calibration.

Validation Qualifiers

B	Not detected substantially above the level reported in laboratory or field blanks.
K	Analyte present. Reported value may be biased high. Actual value is expected to be lower.
N	Tentative Identification. Consider present. Special methods may be needed to confirm its presence or absence in future sampling efforts.
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
L	Analyte present. Reported value may be biased low. Actual value is expected to be higher.
U	Not detected. The associated number indicates the approximate sample concentration necessary to be detected.
UJ	Not detected, quantitation limit may be inaccurate or imprecise.
UL	Not detected, quantitation limit is probably higher.

Reason Codes

GC/MS Organics

c	Calibration failure; poor (RRF) or unstable (%D) response
f	Field duplicate imprecision
l	MS/MSD recovery failure
s	Surrogate failure
t	Tentatively identified Compound
x	Field and/or equipment blank contamination
z	Method blank and/or storage blank contamination

GC and HPLC Organics

c	Calibration failure; poor or unstable (%D) response
f	Field duplicate imprecision
g	Dual column confirmation imprecision
l	MS/MSD recovery failure
s	No confirmation column
x	Trip blank contamination
z	Method blank and/or storage blank contamination

Inorganics and Conventionals

f	Field duplicate imprecision
m	MS/MSD recovery failure
p	Preparation blank contamination
s	Serial dilution failure

5.0 FATE AND TRANSPORT ASSESSMENT

This section discusses the fate and transport of site-related COPCs identified in the nature and extent assessment. Primary fate and transport mechanisms occurring at the site are discussed. The objective of the fate and transport analysis is to identify the primary mechanisms affecting the distribution and migration of COPCs and their ultimate fate. COPCs identified at the sites are summarized in the following table.

COPCs from Nature and Extent Assessment

Human Health Soil COPCs	Soil Constituents Above SSL DAF20	Human Health Groundwater COPCs
Aluminum (SWMUs 35, 37, 38 & AOC Q) Chromium (SWMUs 35, 37, 38 & AOC Q) Lead (SWMU 35) Manganese (SWMU 38 & AOC Q) Mercury (SWMU 37) Aroclor 1254 (SWMUs 35, 37, 38 & AOC Q) Aroclor 1260 (SWMU 35) Nitroglycerin(SWMU 35)	Chromium (SWMUs 35, 37, 38 & AOC Q) Dieldrin (SWMU 37) Aroclor 1254 (SWMU 35) TCE (SWMU 37) 2,4-DNT (SWMU 37)	Manganese(SWMUs 35, 37, 38 & AOC Q) Chloroform(SWMUs 35, 37, 38 & AOC Q) Alpha-BHC (SWMU 37) Heptachlor Epoxide (SWMU 37)

The potential for transport of chemicals in environmental media is largely controlled by the physiochemical properties of the chemicals and the matrix through which they travel or migrate. Table 5-1a describes the physiochemical properties of chemicals that affect their fate in environmental media. Table 5-1b describes the fate processes affecting metals including: ion exchange, chemical speciation, and oxidation-reduction potential. Table 5-1c describes the fate processes affecting organic chemicals including: sorption, volatilization, hydrolysis, and abiotic and biotic degradation. Chemicals can be transported with little attenuation or retardation due to these fate processes or they can be delayed or transformed so that minimal migration occurs. The physical and chemical properties of organic COPCs detected in soil and/or groundwater are summarized in Table 5-2.

Primary fate and transport mechanisms for COPCs potentially present at the site include the following:

- Volatilization of chemicals from soil and groundwater;
- Erosion of particulate-bound chemicals from soil;
- Degradation of chemicals in soil and groundwater;
- Leaching of chemicals from soil with infiltrating water; and
- Transport of chemicals with groundwater flow.

Fate and transport processes for site media are discussed in the following sections.

5.1 FATE AND TRANSPORT - SOIL

Fate and transport processes for soil are discussed in the following sections including volatilization, erosion and mass transport, and degradation of chemicals in soil, and leaching of chemical from soil with infiltrating water.

5.1.1 Volatilization

Volatilization can significantly affect the distribution of a chemical in the environment. This process will result in the mass and concentration of a chemical in soil and/or groundwater as the chemical volatilizes to soil gas and ultimately discharges to the atmosphere. Volatilization reactions are most significant in surface soil that is in direct (or near-direct) contact with the atmosphere. These reactions may also occur in groundwater with VOCs. Chemical volatility is typically quantified by a chemical's Henry's constant, which may be calculated from the chemical's vapor pressure, molecular weight, and solubility. The lower

the Henry's constant, the less volatile the chemical. Values of Henry's constant for soil COPCs are summarized in Table 5-2.

One VOC was identified as a COPC for the soil-to-groundwater migration pathway at SWMU 37 based on two detections in subsurface samples above calculated site-specific SSLs. Low concentrations of VOCs were detected in sludge and soil at SWMU 35, SWMU 37, SWMU 38, and AOC Q and therefore, volatilization is not expected to be a significant influence on the fate of these compounds in soil. Other COPCs at the sites are characterized by low Henry's constants (i.e., < 0.01) and are not VOCs, and therefore, volatilization is not expected to be a significant influence on the fate of these compounds at SWMU 35, SWMU 37, SWMU 38, and AOC Q.

5.1.2 Erosion Processes in Soil

Erosion processes can substantially affect the distribution of soil-bound particulates in the environment and thus influence the distribution of constituents in soil. High winds can scour fine particles from the soil surface and redistribute these particles downwind. Mass transport from surface water runoff during heavy precipitation events can also scour fine soil particles from surface soil, eventually depositing the particles during sedimentation downstream. This potential migration pathway is unlikely due to the presence of constituents of concern location primarily within the drying beds, which are topographically lower than surrounding areas and have internal drainage. Potential migration of COPCs at the site by wind erosion or mass transport is unlikely a significant pathway given that the site areas are covered by heavy vegetation cover (field grass). Chemical sampling did not indicate evidence of transport of COPCs outside of identified disposal areas.

5.1.3 Degradation of Chemicals in Soil

Many organic chemicals that are found in the environment are subject to naturally occurring biotic (biologically based) and abiotic (non-biologically based) transformation reactions. These reactions result in degradation of the chemical. Biodegradation reactions can occur under aerobic (in the presence of oxygen) and anaerobic (in the absence of oxygen) conditions. During biodegradation, naturally occurring microorganisms in the subsurface transform a chemical to another state as a direct or indirect consequence of their metabolic processes. In many cases, biodegradation reactions break down organic chemicals to less toxic forms.

Several naturally occurring abiotic reactions can significantly affect the fate of chemicals in the environment. Common abiotic reactions include photodegradation and hydrolysis. Photodegradation is the process of decomposition of a chemical upon exposure to radiant energy such as the action of light, and is most significant to chemicals in surface soil that are in direct contact with sunlight. Hydrolysis is the degradation reaction of the chemical with components of water (e.g., hydroxyl and hydronium ions) and is therefore most important in saturated environments.

5.1.3.1 Metals

Metal COPCs, such as aluminum, calcium, chromium, copper, lead, manganese, and mercury will not be significantly influenced by degradation processes in soil.

5.1.3.2 Pesticides - Dieldrin

Pesticides were detected at low concentrations in soil at the site. Dieldrin was identified as a COPC for the soil-to-groundwater migration pathway. Dieldrin does not degrade readily in soil or water. Most dieldrin adsorbs strongly to soil and is extremely resistant to biodegradation, persisting for many years in the upper soil layers.

5.1.3.3 PCBs

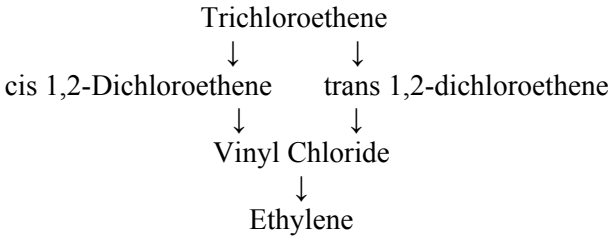
PCBs are very persistent in the environment and are extremely resistant to oxidation and hydrolysis. PCBs are resistant to chemical degradation by oxidation or hydrolysis (HSDB 2007). Aroclors are PCB

mixtures of more than 90 different congeners of chlorobiphenyl. Detected Aroclors at the site have a high degree of chlorination (54% for 1254 and 60% for 1260), which contain higher proportions of the more heavily chlorinated congeners. The persistence of PCBs generally increases with an increase in the degree of chlorination. Aroclor 1254 and 1260 are generally resistant to biodegradation in soil, with limited degradation involving anaerobic reactions, which result in reductive dechlorination to lower chlorinated PCBs; however, this degradation does not necessarily lead to a reduction in toxicity (HSDB 2007). Some biodegradation of lower chlorinated PCBs can occur under aerobic conditions through biotic degradation by microorganisms. Lower chlorinated PCBs tend to degrade more readily than higher chlorinated PCBs.

5.1.3.4 VOCs

VOCs were detected at low concentrations in soil at the sites. TCE was identified as a COPC for the soil-to-groundwater migration pathway. TCE is resistant to aerobic degradation in soil although biodegradation may proceed co-metabolically. Under anaerobic conditions, TCE is slowly biodegraded through reductive dechlorination, with the extent and rate of degradation dependant on the degree of the reducing environment. The reductive dechlorination pathway for TCE is shown below. Degradation by products of TCE have not been detected in soil, sludge, or groundwater samples collected at SWMU 35, SWMU 37, SWMU 38, and AOC Q.

TCE Degradation Pathway – Reductive Dechlorination



5.1.3.5 Explosives – 2,4-DNT and Nitroglycerin

2,4-DNT is an impurity of trinitrotoluene (TNT) and may undergo some degradation in soil by microorganisms with a reduction of the nitro group to form amino groups including 4-amino-2-nitrotoluene and 2-amino-4-nitrotoluene. DNT may undergo photolysis in uppermost surface soil layers based on a rapid rate of photolysis observed in water. DNT is not expected to undergo hydrolysis in soil due to a lack of functional hydrolyzable functional groups (HSDB 2007). Degradation by products of 2,4-DNT have not been detected in soil, sludge, or groundwater samples collected at SWMU 35, SWMU 37, SWMU 38, and AOC Q.

Nitroglycerin undergoes rapid biodegradation using batch reactors and digestors but its rate of biodegradation in soil is unknown. Hydrolysis of nitroglycerin in soil may be important under alkaline conditions but is not expected to be an operable degradation process at the site due to the neutral pH of the soil (HSDB 2007).

5.1.4 Leaching of Chemicals from Soil to Groundwater

Chemicals in soil have the potential to migrate to greater depths with infiltrating water. As precipitation infiltrates, chemicals may be leached from the soil and carried to greater depths and potentially to groundwater. Factors affecting leaching are discussed below followed by specific assessments for COPCs identified in Section 4.0 for the soil-to-groundwater migration pathway based on comparisons to default DAF20 SSLs. The degree to which a chemical is leached is strongly influenced by the chemical's tendency to partition to the solid or aqueous phases, which is largely a function of the chemical's solubility and particle affinity.

Water Solubility

Water solubility of a chemical is the mass of chemical that will dissolve in a unit volume of water at a specific temperature. Chemicals with a high solubility can often be readily dissolved in water and therefore are susceptible to being mobilized from the soil matrix with infiltrating water and migrating downward to groundwater. Chemicals with a low solubility tend to partition to soil.

The solubility of organic chemicals is typically a function of the hydrophobic nature of the chemical. Many organic chemicals are non-polar and therefore do not dissolve readily into water, which is a polar solution. Several of the COPCs identified in soil at the sites, such as PCBs, have low water solubility. Water solubility data for COPCs are summarized in Table 5-2.

Adsorption

The aqueous concentration of chemicals in soil systems can also be substantially influenced by adsorption reaction to the soil matrix. Adsorption is the ability of a substance to bind to the surface of soil particles from reactions that occur between the chemical and the soil particle surface. Organic compounds are frequently non-polar, and therefore, tend to interact with organic matter commonly associated with the soil matrix. The tendency for a chemical to be adsorbed to the organic fraction of soil (or sediment) can be measured by the chemical's organic carbon partition coefficient (K_{oc}). The lower the K_{oc} values the more leaching potential from soil to water as summarized below. Organic compounds with a K_{oc} less than 100 liters per kilogram (L/kg), such as chloroform, have a high potential to leach from soil to water. Progressively higher values of K_{oc} greater than 500 L/kg indicate lower leaching potential. Organic compounds with K_{oc} values in the range of 1E+04 to 1E+06 L/kg, such as PCBs, are generally immobile or nearly immobile in soil. Values of K_{oc} for COPCs are summarized in Table 5-2.

Site-specific distribution coefficients (K_d) can be estimated for each organic COPC, as the product of the K_{oc} of the chemical and the fraction of the organic carbon (f_{oc}) in the soil matrix. The distribution coefficient is a measure of the ratio of chemical mass that partitions to the solid and liquid phases under equilibrium conditions. The fraction of organic carbon in site soil is estimated as 0.62% based on physical data collected at the sites. An order of magnitude higher organic carbon level was measured in a sludge sample collected from SWMU 35 (4%) and in soil immediately below this sludge (9%). Calculated K_d values are presented in Table 5-2. The relatively mobility of site COPCs for the soil-to-groundwater migration pathway have been estimated in the following table based on solubility, K_{oc} and K_d values.

Relative Mobility of COPCs in Soil for the Soil-to-Groundwater Migration Pathway

Immobile	Slight	Low	Moderate	High	Very High
Aroclor 1254	Chromium	Dieldrin	TCE	2,4-DNT	None

COPCs classified as immobile, slightly mobile, or low are unlikely to leach from soil to groundwater at levels of potential concern. Other factors that will influence the degree of leaching for COPCs with a higher mobility include: source area size, concentrations detected, and soil type and permeability.

5.1.4.1 Metals

Chromium was detected in one or more samples at concentrations at each site above their SSL DAF20s and facility-wide background point estimates. Metals detected above facility background without soil-to-groundwater SSLs included: aluminum, lead, and mercury.

Aluminum

Aluminum compounds generally exist in soil in the form of silicates, hydroxides, and oxides. During soil acidification, aluminum ions are released from silicates (i.e., solubilized). At pH values above 5, aluminum ions become strongly bound to soil and exist predominantly in an undissolved form such as

gibbsite (HSDB 2007 and ATSDR 1999c). The adsorption of aluminum to clay surfaces is a major factor in controlling aluminum mobility and has been observed to be very rapid (ATSDR 1999c). Aluminum is expected to be strongly adsorbed to soil and sludge at the site due to its neutral pH (above 5.5). Dissolved aluminum was not detected in groundwater samples collected at the site.

Chromium

The fate of chromium in soil is dependent on the speciation of chromium, which is a function of oxidation reduction potential and pH of the soil. Chromium is typically found in the III valence state, which has very low solubility and low reactivity resulting in low mobility in the environment. The neutral pH soil and sludge at the site will reduce the mobility and leachability of chromium. Site data do not indicate appreciable leaching of chromium to soil below the sludge layer. Dissolved chromium was not identified as a COPC in groundwater, with detected concentrations below the adjusted T-RBC.

Lead

Most lead is retained strongly in soil and very little leaches to groundwater. Elevated lead concentrations above 400 mg/kg were limited to two surface soil/sludge samples collected from the SWMU 35 drying bed. Soil samples collected from below the sludge layer did not indicate appreciable leaching of lead to subsurface soil at levels above background. Dissolved lead was not detected in site groundwater.

Mercury

Mercury has been detected in site surface soil and sludge samples collected from inside the drying beds at levels above the background point estimate of 0.13 mg/kg. Subsurface samples collected below the sludge had mercury concentrations below the background point estimate. Mercury compounds released to soil tend to be strongly adsorbed to soil and typically do not significantly leach. Adsorption of mercury increases with the percent of organic matter in the soil. In contrast to most other metals, acidification of soils does not increase the solubility of mercury compounds. Inorganic mercury compounds can be methylated by microorganisms that are indigenous to the soil environment. This process is mediated by various microbial populations under both aerobic and anaerobic conditions. Sulfur-reducing bacteria are responsible for most of the mercury methylation in the environment; however, yeast populations are also able to methylate mercury (HSDB 2007). Mercury is expected to have low mobility in the site soil and sludge contained in the drying bed given its low mobility and appreciable organic matter present in the sludge. Mercury was not detected in site groundwater.

5.1.4.2 PCBs

PCBs have a low solubility in water and high K_{oc} values, and will tend to be immobile in the environment and remain adsorbed to soil (Table 5-2). At SWMU 35, Aroclor 1254 was detected in 1 of 22 soil samples at a concentration higher than its SSL. PCBs are not considered a potential concern for the soil-to-groundwater migration pathway given their immobile nature, the limited detections above the SSL, the lack of detected concentrations above SSLs in the subsurface soil, and the lack of detections in site groundwater.

5.1.4.3 VOCs

The VOC COPC identified for the soil-to-groundwater migration pathway was TCE at SWMU 37. This compound has moderate solubility, a lower K_{oc} value, and high mobility in subsurface soil (Table 5-2). At SWMU 37, TCE was detected in 2 of 9 soil samples collected at low-level concentrations (6.8 and 63 µg/kg) above its SSL DAF20 (0.26 µg/kg). This chemical is not considered at potential concern for the soil-to-groundwater migration pathway given the infrequent low-level detections, lack of identified source area, and the lack of detections in site groundwater.

5.1.4.4 Pesticides

The pesticide COPC identified for the soil-to-groundwater migration pathway was dieldrin at SWMU 37. Pesticides have low mobility in the subsurface due their lower solubility and higher K_{oc} values and therefore will tend to remain absorbed to soil (Table 5-2). At SWMU 37, dieldrin was detected at concentrations above its SSL DAF20 in one soil samples collected from the surface soil/sludge within the drying bed. Appreciable leaching of dieldrin to subsurface soil below sludge was not apparent. Dieldrin is not considered a potential concern for the soil-to-groundwater migration pathway given its low mobility in soil, single detection above its SSL DAF20, limited apparent leaching relative to the depth of groundwater, and the lack of detections of dieldrin in site groundwater.

5.1.4.5 Explosives

The explosive COPC identified for the soil-to-groundwater migration pathway was 2,4-DNT at SWMU 37. It has a moderate solubility in water. The K_{oc} values are moderate for DNT mixtures. Based on their solubility and K_{oc} values, explosives are expected to have some mobility in soil and potential to leach to groundwater if present at sufficiently high concentrations. 2,4-DNT was detected in 3 of 24 samples with one sample above its SSL DAF20. Appreciable leaching of 2,4-DNT to subsurface soil below surface soil/sludge was not observed at concentrations above the SSL DAF20. 2,4-DNT is not considered a potential concern for the soil-to-groundwater migration pathway given the lack of appreciable leaching to subsurface soil, limited detections above the SSL, and the lack of detections in site groundwater.

5.2 FATE AND TRANSPORT - GROUNDWATER

Fate and transport processes for site-related COPCs in groundwater are discussed in the following sections. COPCs identified in groundwater include: manganese and chloroform (all sites) and alpha-BHC, and heptachlor epoxide (SWMU 37).

5.2.1 Volatilization

Volatilization of a chemical from groundwater will result in a reduction of its mass and concentration as the chemical volatilizes to soil gas and ultimately discharges to the atmosphere. This process may also occur in groundwater with VOCs. Some volatilization of chloroform may occur in site groundwater under ambient conditions due to its higher Henry's constant and volatility, and therefore, may have some influence on the fate of this compound in the subsurface.

5.2.2 Degradation of Chemicals in Groundwater

Inorganic groundwater COPCs are not subject to transformation and degradation in groundwater.

5.2.2.1 Chloroform

Chloroform will tend to persist in groundwater under aerobic conditions, where dissolved oxygen levels are greater than 0.5%. Degradation of chloroform may occur in groundwater under anaerobic conditions if appropriate microbial bacteria are present (USGS 2006). In this case, chloroform (trichloromethane) would be transformed to dichloromethane (methylene chloride) by reductive dechlorination (dehalogenation). Monitored groundwater conditions in the area of the SWMU 35 sludge drying bed range from anaerobic to aerobic and therefore may not be strongly conducive to degradation of chloroform, although the levels of chloroform detected are less than 1 µg/L. In the area of SWMU 37, SWMU 38, and AOC Q, groundwater conditions are generally aerobic based on dissolved oxygen (0.88% to 6.34%) and ORP readings and therefore would not be conducive to degradation of chloroform, although the levels of chloroform detected in the associated monitoring wells are low ranging from non detect to less than 2 µg/L.

5.2.2.2 Pesticides

Alpha-BHC

Alpha-BHC is an isomer form of BHC. Technical-grade BCH, a pesticide previously used in the United States, typically contained alpha, beta, and delta forms of BHC in addition to the primary gamma form. BHC can be persistent in the environment but some degradation may occur in the environment primarily under anaerobic conditions. In the area of SWMU 37, groundwater conditions are generally aerobic based on dissolved oxygen (0.88% to 6.34%) and ORP readings therefore would not be favorable for the reductive degradation pathway.

Heptachlor Epoxide

Heptachlor epoxide is not produced commercially, but rather is formed by the chemical and biological transformation of heptachlor in the environment. Heptachlor epoxide adsorbs strongly to soil and is extremely resistant to biodegradation (HSDB 2007). Heptachlor epoxide remaining in groundwater at the site is not expected to significantly biodegrade with other fate processes such as dispersion likely acting to reduce concentrations over time.

5.2.3 Dispersion Processes in Groundwater

As water containing dissolved phase constituents flows through a porous medium it will mix with water not containing dissolved phase constituents and as a result it will dilute (mechanical dispersion). Mixing that occurs along the direction of groundwater flow is called longitudinal dispersion and mixing that occurs perpendicular to the direction of groundwater is called lateral dispersion. Longitudinal dispersion is influenced by pore size, flow path length through the porous media, and the friction in the pore. Lateral dispersion occurs due to the splitting and branching of water as it flow paths through porous media.

Dispersion processes are likely an important process influencing the fate and transport of dissolved phase constituents in site groundwater given the porous alluvium and variety of interconnections that can exist in weathered and fractured bedrock. Dispersion can also occur through the matrix of the rock.

5.2.4 Adsorption and Retardation

The migration rate of organic chemicals in groundwater can be slowed relative to groundwater flow due to attenuation reactions such as adsorption, particularly when flowing through porous media. In porous media, the effect of adsorption reaction on chemical migration rates is typically quantified by using a retardation factor (R), which may be estimated from the chemical-specific K_d in liters per kilogram, soil bulk density (ρ_b) in kilograms per liter and porosity (n). However, the rates of retardation in fractured and karst bedrock aquifers are difficult to quantify and therefore, have not been estimated for site groundwater. Based on the chemical and physical properties of chloroform, lower rates of adsorption and retardation are expected for these constituents in site groundwater.

5.3 FATE AND TRANSPORT SUMMARY

Volatilization was not identified as an important fate and transport process at the sites given the low concentrations of VOCs detected in soil and sludge. Mass transport and erosion of COPCs contained in sludge was not observed outside of the drying beds. Significant leaching of organic and inorganic COPCs from the calcium sulfate sludge to underlying soil was not apparent from the data collected.

Groundwater samples collected from the drying bed areas did not indicate appreciable leaching of constituents detected in calcium sulfate sludge to groundwater. Although low level concentrations of chloroform were detected at SWMU 35, SWMU 37, and SWMU 38/AOC Q, chloroform was not detected in soil at the sites and chloroform was detected in upgradient wells at the sites. It is important to note that studies and groundwater investigations have shown the presence of chloroform in most groundwater samples collected at the facility regardless of location. The concentrations of chloroform detected in monitoring wells at the sites are low level concentrations below the range of chloroform levels

present in the water transmitted through water lines at the facility. The sites are located downgradient of developed areas containing water lines that could be leaking, which may have been the source of chloroform. In addition, as presented in Section 6.0 chloroform was not identified as a risk driver in the human health risk assessments. At SWMU 37, data suggests the site is not the source of pesticides in groundwater since the pesticides detected in groundwater were not detected in soil at the site and pesticides were also detected in background well 37MW1. At SWMU 38, a specific site-specific source related to disposal activities for the manganese concentrations detected above the T-RBC in well 38MW3 was not identified. Manganese concentrations within material in the drying bed (87 to 550 mg/kg) were similar to manganese concentrations in soil outside the drying bed (222 to 600 mg/kg) where no indication of impacts from site use were noted (i.e., no sludge present). Manganese concentrations at the site also were within the low-to-mid range of concentrations of manganese in the background data set (16.7 to 2,040 mg/kg). The occurrence of dissolved manganese at concentrations above the T-RBC at one well location 38MW3 may be due to natural geologic conditions (i.e., weathering of bedrock containing manganese and alluvial deposition).

Table 5-1a
Chemical Properties Affecting Fate and Transport
SWMUs 35, 37, 38, and AOC Q RFI Report
Radford Army Ammunition Plant, Radford, VIrginia

Property	Description
Specific Gravity	Specific gravity is the ratio of the density of a chemical to the density of water and its tendency to float (specific gravity <1) or sink (specific gravity >1) in water. Chemicals that are immiscible in water can exist as non-aqueous phase liquids and are referred to as light non-aqueous phase liquid if their specific gravity is less than one, or dense non-aqueous phase liquid if their specific gravity is greater than one.
Water Solubility	Water solubility of a chemical is the mass of chemical that will dissolve in a unit volume of water at a specific temperature. Chemicals with a high solubility tend to remain dissolved in water rather than partition to soil or sediment are less likely to volatilize, and more likely to biodegrade. Chemicals with a low solubility tend to partition to soil or sediment, are more likely to volatilize and less likely to biodegrade.
Vapor Pressure	Vapor pressure of a chemical is how readily it will volatilize to the atmosphere. Volatilization from water is dependent upon vapor pressure and Henry's law constant. Vapor pressures in their pure state range from 0.001 to 760 millimeters mercury (mm Hg) for liquids to less than 1E-10 mm Hg for solids.
Henry's Law Constant	Henry's law constant of a chemical is a measure of how a chemical will partition between air and water at equilibrium. It is the ratio of the vapor pressure to the water solubility (atm-m^3/mole) and can be used to calculate the rate of volatilization of a chemical from water. Chemicals with a high Henry's law constant more readily volatilize from water.
Organic Carbon Partition Coefficient (K_{oc})	K_{oc} is a measure of the tendency for a chemical to be sorbed to the organic fraction of soil and sediment. The lower the K_{oc} values the more leaching potential from soil or sediment to water. Chemicals with a K_{oc} less than 100 milliliters per gram (mL/g) have a high potential to leach from soil or sediment to water, while K_{oc} values in the range of 100 to 500 mL/g indicate a moderate leaching potential.
Octanol-Water Partition Coefficient (Ko_w)	K_{ow} describes the partitioning of an organic chemical between a polar phase (water) and a relatively nonpolar phase (1-octanol). It is equated to the partitioning (sorption) in an aquifer of a chemical between the water and the porous media organic content. A chemical with a high K_{ow} is hydrophobic and may be relatively immobile in an aqueous system but may be mobilized in the presence of an organic solvent.

Table 5-1b
Fate Processes Affecting Metals
SWMUs 35, 37, 38, and AOC Q RFI Report
Radford Army Ammunition Plant, Radford, Virginia

Process	Description
Ion Exchange	Ion exchange is a specific category of adsorption due to an affinity of the solid surface for the chemical. Ion exchange occurs when the adsorbent charge deficiency can be neutralized more efficiently by ions in solution than by those ions currently adsorbed. As an example, if sodium ions (monovalent) have accumulated at the interface and suddently calcium ions (divalent) appear, the surface excess can be more efficiently neutralized by the calcium ions than by the sodium ions; thus, the sodium ions will desorb and the calcium ions will adsorb and an exchange of ions will occur. Clay minerals are frequently the dominant source of ion exchange in the subsurface. The surface charge of clays and many other mineral surfaces is a function of pH. At low pH (excess hydrogen ions), the surface can exhibit a positive net charge while at higher pH (excess hydroxyl ions) the surface can exhibit a negative charge (Knox et al 1993). The surface area of the exchange site significantly influences the level of adsorption; this parameter is typically discussed in terms of the cation exchange capacity (CEC) of the medium and is expressed in units of milliequivalents of exchanging cations per 100 grams of solids (meq/100 g). CEC values indicate the likely type of clay present; the higher the CEC value the greater the absorption potential.
Chemical Speciation	Most metals occur in more than one ionic form (species) in solid and aqueous media. These species form from hydrolysis, oxidation reduction reactions, and complexation reactions, which may have different valences and mobilities in soil water, groundwater, and surface water due to different affinities for adsorption and different solubilty controls. Simple ionic specifies frequently combine ligands to form ionic or neutral-charge aqueous complexes. Environmental conditions that affect speciation of metals include pH, redox potential, and organic ligands.
Oxidation Reduction Potential (ORP)	Redox refers to the transfer of electrons and resultant specifies change of ions or compounds. Oxidation is the loss of electrons and reduction is the gain of electrons. Redox can cause changes in the mobility of many metals, such as site COPCs iron, manganese, and arsenic. The ability of a redox reaction to occur is a function of the redox potential. Redox potential is typically defined in terms of the negative logarithm of the free-electron activity (pE). The redox potential can also be expressed in terms of volts (Eh). Low values of pE indicate high electron activity and favor electron-rich species (reduced). High values of pE indicate low electron activity and favor electron-poor species (oxidized) (Knox et al 1993).

Table 5-1c
Fate Processes Affecting Organics
SWMUs 35, 37, 38, and AOC Q RFI Report
Radford Army Ammunition Plant, Radford, Virginia

Process	Description
Sorption	Sorption includes the processes of adsorption and absorption. Adsorption is a mass transfer process where a substance is transferred from a phase to the surface of a medium (e.g. soil or sediment) where it is bounded by chemical or physical forces. Absorption is the partitioning between two phases (Knox et al. 1993). Sorption reactions are either sorbent or solvent-motivated. Sorbent-motived reactions occur when there is an attraction between the sorbent and the solute and the chemical accumulates at the surface due to the affinity of the surface for the chemical. Solvent-motivated reactions occur when the chemical is hydrophobic, such as nonionic organics, where the chemical will accumulate at an interface or partition into a nonionic phase (associate with the organic content of the medium). For nonionic organics, the fraction of organic content (foc) of the subsurface material is the dominant soil characteristic affecting sorption (Knox et al. 1993). Primary indicators of the partitioning of a chemical are the organic carbon water partition coefficient (Koc), soil/water distribution coefficient (Kd), the octanol water partitioning coeffient (Kow), and the calculated retardation factor.
Hydrolosis	Hydrolysis is the degradation process via chemical reactions (oxidation, reduction, hydrolysis) without the participation of organisms. Hydrolysis is a chemical decomposition process that uses water to split chemical bonds of substances. There are two types of hydrolysis, acid and enzymatic. Hydrolysis is limited to chemical that contain hydrolyzable groups and is effected by the contaminants hydrolysis half life.
Volatilization	Volatilization is the process by which a contaminant changes from a liquid phase to a gas phase. This process applies to organic comtaminants migrating from the soil or surface water. Volatile organic chemicals are a class of chemicals that easily evaporate or mix with the atmosphere. The potential volatilization of a chemical is affected by the compounds vapor pressure, solubility, organic carbon partitioning coefficient, and the temperature.
Abiotic Degradation	Abiotic degradation includes degradation processes in which organisms do not participate. Photolysis describes the abiotic degradation process via photochemical reactions such as photooxidation, photomineralisation without the participation of organisms. As described above, hydrolysis is an additional process of abiotic degradation.
Biotic Degradation	Biotic degradations the process in which chemical degradation of a contaminant is aided by soil organisms. Biotic degradation can be either aerobic or anaerobic. The rate of metabolism/cometabolism is affected by the contaminant's biochemical oxygen demand, chemical oxygen demand, degree of halogenation, etc. Reactions include but are not limited to oxidation/reduction and hydrolysis, as described above.

mm Hg = Millimeters Mercury

6.0 HUMAN HEALTH RISK ASSESSMENT

This HHRA evaluates the probability and magnitude of potential adverse effects on human health associated with exposure to site-related chemicals in soil and groundwater. SWMUs 35 and 37 are evaluated separately while SWMU 38 and AOC Q are evaluated together due to their close proximity and the use of AOC Q as an overflow pond for SWMU 38 resulting in similar depositional histories. Refer to Section 2.0 for additional information regarding the sites' backgrounds. The HHRAs were conducted for the sites consistent with guidance included in EPA's *Interim Final Risk Assessment Guidance for Superfund* (RAGS), as well as other USEPA guidance (USEPA 1989; 1991; 1997b; 2001a,b; 2002c; and 2004b). Guidance documents are also noted on the RAGS Part D tables provided in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q).

This HHRA consists of the following seven sections:

- **Section 6.1: Data Summary and Selection of COPCs:** Relevant site data are gathered, examined, and discussed. Basic constituent statistics and screening levels are summarized. COPCs are identified by comparison to screening criteria as discussed in Section 6.1.2;
- **Section 6.2: Exposure Assessment:** Potentially exposed populations (i.e., receptors) and exposure routes are identified, and exposure point concentrations (EPCs) are calculated for COPCs. Standard exposure factors and health-protective assumptions are used to assess the magnitude, frequency, and duration of exposure for each exposure route and intakes are calculated;
- **Section 6.3: Toxicity Assessment:** Toxicity criteria for COPCs are gathered and presented;
- **Section 6.4: Risk Characterization:** Quantitative risks and hazards are estimated and summarized by combining toxicity criteria with intakes for each exposure route;
- **Section 6.5: Summary:** The results of the HHRA are summarized;
- **Section 6.6: Uncertainties Analysis:** Uncertainties, "including uncertainties in the physical setting definition for the sites, in the models used, in the exposure parameters, and in the toxicity assessment" (USEPA 1989) are discussed; and
- **Section 6.7: Conclusions:** The conclusions of the HHRA are presented.

As previously stated, the tabulated risk assessment results are presented in accordance with USEPA guidance described in RAGS: Volume I - Human Health Evaluation Manual (Part D, Standardized Planning, Reporting, and Review of Superfund Risk Assessments) (USEPA 2001b). RAGS Part D requires the risk assessment results to be presented in a series of standardized tables, which are presented in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q).

6.1 DATA SUMMARY AND SELECTION OF COPCS

6.1.1 Data Summary

Table 6-1 identifies the samples used in the SWMU 35, SWMU 37, and SWMU 38/AOC Q COPC screenings for soil, respectively. Refer to Section 4.0 for complete data tables for detected analytes for each media and disposal area. Additional information regarding the data used in the HHRAs is summarized below:

- If a constituent was measured by two methods, results from the more sensitive analytical method were used. For example, explosives were analyzed as part of the SVOC method, as well as, by a explosives specific method. Results from the specific method were used;
- J-flagged data (estimated concentration) and B-flagged data (detected in an associated blank) are considered detections and are used without modification;

- Rejected results (R-flagged) are not used;
- Chemicals that were not detected in at least one sample were considered as uncertain analytes in the evaluation of risk; and
- Data from duplicate sample pairs are averaged and treated as one result. If an analyte is detected in one of the sample pair, one half the detection limit of the non-detect is averaged with the detected result and the result is considered detected.

Additional information regarding specific soil and groundwater samples used in the HHRA is provided in Sections 6.1.1.1 and 6.1.1.2.

6.1.1.1 Surface Soil and Total Soil

Prior to the RFI, historical soil analytical data (1990 and 1992) were considered screening level data and excluded from the risk assessment given the age of the data, the use of non SW-846 analytical methods, the lack of available data validation reports/information, and the availability of sufficient newer validated SSP and RFI data to more appropriately characterize conditions at the site. As presented in Table 6-1, soil samples collected during sampling events completed in 2003 for the SSP and 2007 for the RFI were used for the COPC screenings. In addition as presented in Table 6-1, the soil samples for each area have also been divided into surface soil (0 to 1 ft bgs) and subsurface soil (1 to 15 ft bgs). The two soil data groupings used for COPC screenings and the HHRAs are surface soil (0 to 1 ft bgs) and total soil (0 to 15 ft bgs). Total soil data grouping consists of combining surface and subsurface soil to address mixing of potential soil constituents during construction or land development activities. Soil samples collected a depth of greater than 15 ft bgs were excluded from the HHRAs since it is unlikely soil below this depth would be disturbed and mixed with surface soil during excavation.

Ten surface soil samples and 12 subsurface soil samples were used for the HHRA for SWMU 35, 10 surface soil samples and 11 subsurface soil samples were used for the HHRA for SWMU 37, and 14 surface soil samples and 16 subsurface soil samples were used for the HHRA for SWMU 38/AOC Q. Figures 3-1, 3-2, and 3-3 show the soil sample locations for SWMU 35, SWMU 37, and SWMU 38/AOC Q, respectively.

6.1.1.2 Groundwater

Groundwater samples collected during the sampling events completed in February 2008, resampling in June 2008, and June 2010 for the RFI were used for the COPC screenings. Four wells (35MW1, 35MW2, D-2, and D-4) were sampled at SWMU 35, four wells (37MW1, 37MW2, 37MW3, and 37MW4) were sampled at SWMU 37, and three wells (38MW1, 38MW2, and 38MW3) were sampled at SWMU 38/AOC Q. Data from downgradient and crossgradient wells were used in the COPC screenings (Table 6-1). Dissolved metals data was used in the RFI. Figures 3-1, 3-2, and 3-3 show the groundwater sample locations for SWMU 35, SWMU 37, and SWMU 38/AOC Q, respectively.

6.1.2 Identification of COPCs

COPCs were identified for the sites by comparing the MDC to the following screening levels for each media: USEPA Region III R-RBCs and I-RBCs (surface soil and total soil) and USEPA T-RBCs (groundwater) as presented in the October 2007 USEPA Region III RBC and Alternate RBC Tables (USEPA 2007a). In accordance with USEPA Region III guidance, RBCs for non-carcinogenic chemicals were adjusted downward to a HQ of 0.1 to ensure that chemicals with additive effects were not prematurely eliminated during screening.

For nutrients detected in soil (calcium, potassium, magnesium, and sodium) that have no available RBC, the MDC was compared to the recommended daily allowance (RDA)-derived soil ingestion screening criteria. Table 6-2 presents the equation, exposure parameters, and RDAs used, as well as the calculated

screening criteria for the adult resident and child resident receptors. The lowest screening criterion for each nutrient (e.g., the screening criteria for the child resident) was selected as the screening criterion.

In addition, lead ALs of 400 mg/kg for residential receptors and 750 mg/kg for industrial receptors were used in the COPC identification since toxicity criteria were not available for lead (USEPA 1994).

Analytes detected at a maximum concentration greater than the corresponding adjusted RBC or screening values identified above (or those for which no screening criteria exists) were selected as COPCs. COPC screening tables for each area are presented in Appendices E.1 (SWMU 35), E.2 (SWMU 37) and E.3 (SWMU 38/AOC Q), Tables E.1-2.1 (COPC Determination Detects-Surface Soil), E.1-2.2 (COPC Determination Detects-Total Soil), E.1-2.3 (Non-Detect Screening-Soil), E.1-2.4 (COPC Determination Detects-Groundwater), and E.1-2.5 (Non-Detect Screening-Groundwater) for SWMU 35, and Tables E.2-2.1 (COPC Determination Detects-Surface Soil), E.2-2.2 (COPC Determination Detects-Total Soil), E.2-2.3 (Non-Detect Screening-Soil), E.2-2.4 (COPC Determination Detects-Groundwater), and E.2-2.5 (Non-Detect Screening-Groundwater) for SWMU 37, and Tables E.3-2.1 (COPC Determination Detects-Surface Soil), E.3-2.2 (COPC Determination Detects-Total Soil), E.3-2.3 (Non-Detect Screening-Soil), E.3-2.4 (COPC Determination Detects-Groundwater), and E.3-2.5 (Non-Detect Screening-Groundwater) for SWMU 38/AOC Q. A summary of the results of the human health COPC screenings for the sites are presented in the tables below.

SWMU 35 - Human Health COPCs Identified

Chemical	Surface Soil	Total Soil	Groundwater

Aroclor 1254	X	X	
Cyclohexane [1,2]	X	X	
Methylcyclohexane [1,2]	X	X	
Chloroform			X

Note: [1] COPC identified due to no screening value available
[2] Not carried through the HHRA due to low frequency of detection (1/6 surface soil samples and 1/14 total soil samples)

Also note that a chemical was not carried through the HHRA if the frequency of detection is low in the HHRA data set. For example at SWMU 35, dimethylphthalate was detected in 1 of 22 soil samples collected at low levels; therefore, dimethylphthalate is not carried through the risk assessment. Dimethylphthalate was not detected in groundwater. Other chemicals not carried through the risk assessment due to frequency detection include the following: Aroclor 1260 (SWMU 35), dimethylphthalate and di-n-octylphthalate (SWMU 37), and cyclohexane and methylcyclohexane (SWMU 38/AOC Q). Note that although nitroglycerin at SWMU 35 had a low frequency of detection (1 of 22 soil samples), the detection was above the industrial screening level indicating a potential "hot spot"; therefore, nitroglycerin was carried through the HHRA.

6.2 EXPOSURE ASSESSMENT

The objective of the exposure assessment is to estimate "the type and magnitude of exposures to chemicals of potential concern" (USEPA 1989). When combined with chemical-specific toxicity information (summarized in the toxicity assessment), these exposures produce estimations of potential risks.

6.2.1 Conceptual Site Model/Receptor Characterization

6.2.1.1 SWMU 35

A refined conceptual site model (CSM) for SWMU 35 is presented on Figure 6-1. SWMU 35 is an inactive unit previously used for the drying of calcium sulfate sludge. Calcium sulfate precipitated and settled in settling lagoons then was removed from the lagoons and placed in SWMU 35. The sludge was then removed from SWMU 35 and disposed of in various locations at RFAAP (Dames & Moore 1992). RFAAP reported that "sediment" from SWMU 10 was potentially deposited in SWMU 35, most likely during the early 1980s (Dames and Moore 1994). During the RFI investigation, sludge was encountered in SWMU 35 (approximate sludge thickness of 5 ft). The site consists of a depressed area surrounded by an earthen berm where precipitation and overland flow infiltrate into subsurface soil. Surface water and sediment are not present within the site area; however, the New River is located approximately 120 ft north of the site. Due to the nature of the runoff at the site, the depression of the site prevents runoff from reaching the river. Groundwater is present at approximately 17 to 21 ft bgs with groundwater flow toward the north and the New River.

A refined CSM for SWMUs 37, 38, and AOC Q is presented on Figure 6-2. SWMUs 37, SWMU 38, and AOC Q are inactive units previously used for the drying of calcium sulfate sludge. Calcium sulfate precipitated and settled in settling lagoons then was removed from the lagoons and placed in SWMU 37, SWMU 38, and AOC Q. During the RFI investigation, a surface layer of sludge was encountered in SWMU 37 (approximate sludge thickness of 2 to 4.5 ft) and in SWMU 38/AOC Q (approximate sludge thickness of 0.5 ft). The sites consists of a depressed areas surrounded by earthen berms where precipitation and overland flow infiltrate into subsurface soil. Surface water and sediment are not present within the site areas; however, the New River is located approximately 300-400 ft northwest of the sites. Due to the nature of the runoff at the sites, the depression of the sites prevents runoff from reaching the river. Groundwater is present at approximately 24 to 30 ft bgs with local groundwater flow in the monitored area toward the north and northeast.

Groundwater in the main manufacturing area at RFAAP is not currently used as drinking water. Potentially affected media include surface soil, subsurface soil, and groundwater at the site. While the sites' groundwater discharge may be hydraulically connected to the New River, the completeness of this pathway is unknown. Site-related groundwater impacts were not identified during the assessment of the sites; therefore, an assessment of the New River was not conducted. Residential and recreational areas are located adjacent to the RFAAP. It is unlikely, however, that the land use within the MMA will change significantly in the foreseeable future. The MMA contains many buildings and facilities, and is likely to remain industrial in nature.

The SWMUs are not currently active; therefore, maintenance workers (e.g., groundskeepers) are the most likely receptors under current site conditions. Due to installation security, it is unlikely that trespassers could gain access to the SWMUs; however, risks associated with the maintenance worker are considered protective of the limited exposure experienced by the trespasser. Under future site conditions, maintenance workers continue to be receptors and although the development of the area is unlikely, construction workers and commercial workers may be hypothetical receptors if the area is developed. RFAAP is likely to remain a military installation; therefore, a residential scenario is considered unlikely. However, the residential scenario was evaluated for the sites to assess clean closure requirements under RCRA.

6.2.2 Identification of Exposure Pathways

The potential receptors identified for the sites include current/future maintenance workers, hypothetical future commercial workers, hypothetical future construction workers, hypothetical future child resident, hypothetical future adult resident, and hypothetical future lifetime resident. Carcinogenic risk is assessed for the hypothetical lifetime resident to account for cumulative lifetime risk. The exposure duration for the lifetime resident scenario is assumed to be 30 years total; therefore, for carcinogens, exposures are combined for hypothetical child resident (6 years) and adult resident (24 years). In Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q), Tables E.1-1, E.2-1, and E.3-1 summarize the selection of exposure pathways for each area and receptor listing the rationale for the inclusion or exclusion of each pathway. A conceptual site diagram for the sites is presented on Figure 6-3. The table below summarizes the exposure pathways and media evaluated for each of the potential receptor populations.

Media/Exposure Pathways	Exposure Scenarios			
	Current/Future	Future		
	Maintenance Worker	Commercial Worker	Construction Worker	Resident [1]
Surface Soil				
Ingestion	X			X
Dermal Absorption	X			X
Inhalation of Fugitive Dust	X			X
Inhalation of Outdoor Vapors [2]				
Total Soil [3]				
Ingestion	X	X	X	X
Dermal Absorption	X	X	X	X
Inhalation of Fugitive Dust	X	X	X	X
Inhalation of Outdoor Vapors [2]				
Inhalation of Indoor Vapors [2]				
Groundwater				
Ingestion		X		X
Dermal Absorption		X		X
Inhalation of Outdoor Vapors			X	
Inhalation of Indoor Vapors		X		X
Inhalation of Vapors while Showering [4]				X

X = Quantitative Evaluation

[1] The exposure duration for the lifetime resident scenario is assumed to be 30 years total; therefore, for carcinogens, exposures are combined for hypothetical child resident (6 years) and adult resident (24 years).

[2] VOCs not identified as COPC for soil; therefore, no assessment of vapors.

[3] The evaluation of total soil assumes that construction, excavation, or other activities "mix" the surface and subsurface soil, thus changing the constituent concentrations available on the surface.

[4] Inhalation of vapors while showering is evaluated using the adult resident only.

6.2.2.1 Current/Future Land Use Scenario

One receptor, the maintenance worker, was identified under the current land use scenario. The current maintenance worker is assumed to contact surface soil. It is assumed that the maintenance worker scenario is likely to exist in the future; therefore, exposure to total soil is possible if excavation activities occur in the future.

6.2.2.2 Future Land Use Scenario Only

In the event that construction occurs at the sites, soil that was previously found at depth may be brought to the surface and become available to receptors. Therefore, the future hypothetical industrial use scenarios of the construction worker and commercial worker are assumed to come into contact with total soil at the sites. In addition, potential future exposures to groundwater are evaluated in the HHRA. It is assumed that the commercial worker is exposed to groundwater via tap water. Due to a groundwater depth greater than 15ft, the construction worker is assessed only for the vapor pathway to account potential vapors released to ambient air from groundwater beneath excavation trenches, but is not assessed for the ingestion or dermal contact pathways.

Although the sites are assumed to remain industrial in nature, the residential scenario is evaluated in this HHRA to meet clean closure requirements under RCRA. Due to the presence of a distinct surficial layer of sludge at the sites, the future hypothetical resident is assessed for exposure surface soil and groundwater, as well as, total soil and groundwater.

6.2.3 Calculation of EPCs

The mean concentration of each COPC is estimated and is referred to as the EPC. To account for uncertainty when estimating EPCs from sample data, the 95% upper confidence limit of the mean (95% UCL) is used instead of the mean itself (USEPA 1989). Methods used to calculate 95% UCLs are based on guidance provided in the following documents *Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites* (USEPA 2002b) and *On the Computation of a 95% Upper Confidence Limit of the Unknown Population Mean Based Upon Data Sets with Below Detection Limit Observations* (USEPA 2006).

In general, the method used to calculate a 95% UCL depends on: 1) number of samples, 2) the prevalence of non-detects, and 3) the data distribution (e.g., normal or lognormal). Non-detects introduce uncertainty in the data set because the true concentration may be between zero to just below the detection limit. Therefore, distributional assumptions are difficult to make for COPCs with a high rate of non-detects. ProUCL 4.0 (USEPA 2007b) is used to calculate EPCs for the sites. EPCs for soil COPCs are presented in Tables E.1-3.1 and E.1-3.2 of Appendix E.1 (SWMU 35), Tables E.2-3.1 and E.2-3.2 of Appendix E.2 (SWMU 37), and Tables E.3-3.1 and E.3-3.2 of Appendix E.3 (SWMU 38/AOC Q). EPC calculations for the sites are included in Appendix D.1. EPCs were not calculated for groundwater; therefore, the MDC for COPCs identified for groundwater were used in the risk assessment.

To address the inhalation of fugitive dust from soil exposure pathway, particulate emission factors (PEFs) were used to derive ambient air EPCs for non-volatile soil COPCs. PEFs were calculated in accordance with the Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites (USEPA 2002c). The PEF calculations are provided in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q), Tables E.1-4.4, E.2-4.4, and E.3-4.4.

To evaluate inhalation of VOCs from groundwater, EPCs were calculated for VOCs in air using the models as summarized below. The Johnson and Ettinger model (Johnson et al 1991 – updated 2004) was used to estimate indoor air concentrations of volatiles migrating from groundwater through the soil and into a structure. Spreadsheets for this model were used to estimate air concentrations of VOCs in office buildings and residences for this HHRA. The spreadsheet is found in Appendix E.4 and the results

provided in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q), Tables E.1-4.6, E.2-4.6, and E.3-4.6. Note that VOCs were not identified as COPCs in soil for the sites.

EPCs of VOCs in air due to volatilization from groundwater were estimated for a showering scenario, applicable to the adult resident, using the Foster-Chrostowski (1987) shower room model. The model is provided in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q), Tables E.1-4.7, E.2-4.7, and E.3-4.7.

In the event that excavation work is performed on site, the worker may be exposed to volatile emissions from groundwater below the bottom of the trench. While USEPA does not have a standardized model for estimating concentrations of airborne VOCs in a trench or a pit, the VDEQ provides such a model on their Voluntary Remediation Program (VRP) web site (http://www.deq.state.va.us/vrprisk/). The equation and parameters are given in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q), Tables E.1-4.8, E.2-4.8, and E.3-4.8.

6.2.4 Quantification of Exposure: Calculation of Daily Intakes

For each receptor and pathway, chronic daily intake (CDI, expressed as milligrams of COPC per kilogram body weight per day) for each COPC is estimated by combining the EPC with exposure parameters such as ingestion rate, frequency of contact, duration, and frequency of exposure. In addition, intake parameters are selected so the combination of intake variables results in an estimate of the reasonable maximum exposure for that pathway (USEPA 1989). In addition, intake parameters are selected so the combination of intake variables results in an estimate of the reasonable maximum exposure for that pathway (USEPA 1989).

Intake formulas, exposure parameters, and chemical-specific parameters are provided in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q), Tables E.1-4.1 through E.1-4.8, Tables E.2-4.1 through E.2-4.8, and Tables E.3-4.1 through E.3-4.8. The results of the CDI calculations are presented for each receptor in Appendices E.1 (SWMU 35), E.2 (SWMU 37), E.3 (SWMU 38/AOC Q), Tables E.1-7.1 through E.1-7.10, Tables E.2-7.1 through E.2-7.10, and Tables E.3-7.1 through E.3-7.10.

6.3 TOXICITY ASSESSMENT

The methodology used for classifying health effects from exposure to chemicals is recommended by USEPA and considers chronic exposures. The chronic toxicity criteria were obtained from the October 2007 USEPA Region III RBC Table (available at http://www.epa.gov/reg3hwmd/risk/), which utilizes the following hierarchy:

- Tier 1 - USEPA's Integrated Risk Information System (IRIS);
- Tier 2 - Provisional Peer-Reviewed Toxicity Values (PPRTVs), as developed on a chemical-specific basis by the Office of Research and Development/National Center for Environmental Assessment (NCEA)/Superfund Health Risk Technical Support Center; and
- Tier 3 - other sources of toxicological reference values that include those from Cal EPA, Minimal Risk Levels (MRLs) from Agency for Toxic Substance Disease Registry (ATSDR), and finally the Human Health Effects Assessment Summary Tables (HEAST) toxicity values.

Toxicity criteria used to quantify non-carcinogenic hazards (risk reference doses – RfDs) and carcinogenic risks (e.g., slope factors – CSFs) are presented in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q), Tables E.1-5.1, E.1-5.2, E.1-6.1, and E.1-6-2 for SWMU 35, Tables E.2-5.1, E.2-5.2, E.2-6.1, and E.2-6-2 for SWMU 37, and Tables E.3-5.1, E.3-5.2, E.3-6.1, and E.3-6-2 for SWMU 38/AOC Q.

6.3.1 Health Effects Classification and Criteria Development

According to USEPA's science policy, there are two primary approaches to developing toxicity values or health effects criteria. The non-threshold approach is based on USEPA's scientific policy position that a

small number of molecular events can evoke changes in a single cell or a small number of cells. This is described as a non-threshold initiator mechanism because there is essentially no level of exposure (i.e., a threshold) to a constituent that will not result in some finite possibility of causing an adverse effect. Another assumption stemming from USEPA's science policy is that the dose-response curve is linear at low doses. For most carcinogens, toxicity criteria are based on the non-threshold approach.

The threshold approach is based on the assumption that organisms have repair and detoxification capabilities that must be exceeded by some critical concentration (threshold) before the adverse effect is manifested. For example, an organ can have a large number of cells performing the same or similar functions that must be significantly depleted before the effect on the organ is realized. This threshold view holds that a range of exposures from just above zero to some finite value can be tolerated by the organism without an appreciable risk of adverse effects. Toxicity criteria for non-carcinogens are based on the threshold approach. Furthermore, as additional information regarding the mechanisms of toxicity becomes available, the threshold approach may also apply to some carcinogens (*e.g.*, chloroform).

6.3.1.1 Cancer Slope Factors

For carcinogens, USEPA estimates the excess lifetime cancer risks associated with various levels of exposure by developing CSFs and unit risks. CSFs are expressed in terms of reciprocal dose, as units of: (mg chemical/kg body weight - day)$^{-1}$, and describe the upper-bound increase in an individual's risk of developing cancer over a 70-year lifetime per unit of exposure. Unit risks are expressed either as a reciprocal air concentration, in units of micrograms per meter cubed ($\mu g/m^3$)$^{-1}$ or as a reciprocal drinking water concentration, in units of micrograms per liter ($\mu g/L$)$^{-1}$. Similarly, they are defined as the probability of an individual developing cancer over a 70-year lifetime from exposure to one unit of concentration in air or water. Because regulatory efforts are geared to be protective of public health, including even the most sensitive members of the population, the CSFs are derived using conservative assumptions.

CSFs and unit risks are derived from the results of human epidemiological studies or chronic animal bioassays. Animal studies usually must be conducted using relatively high doses to detect possible adverse effects. Because humans are expected to be exposed to doses lower than doses used in the animal studies, the potential cancer risks at lower doses are estimated by using mathematical models. The data from animal studies are typically fitted to the linearized multistage model to obtain a dose-response relationship. In general, after the data are fit to the dose-response model, the 95% UCL of the slope of the resulting dose-response relationship at low doses is calculated. This upper-bound limit is subjected to various adjustments and an interspecies scaling factor is applied to derive the slope factor or unit risk for humans. Thus, the actual risks associated with a given intake of a potential carcinogen quantitatively evaluated based on animal data are generally regarded as not likely to exceed the risks estimated using these CSFs or unit risks and they may be as low as zero (USEPA 1986). Dose-response data derived from human epidemiological studies are fitted to dose-time-response curves. These models provide rough, but plausible, estimates of the upper limits on lifetime risk. CSFs and unit risks based on human epidemiological data are derived using conservative assumptions and are unlikely to underestimate risks for a given level of exposure.

Weight-of-evidence categories represent an assessment of the amount and quality of the data, which support the finding that specific chemicals and elements can cause cancer in humans. Although USEPA's guideline for carcinogen risk assessment (USEPA 1986) proposes a weight-of-evidence narrative, IRIS currently uses the original alphanumeric classification. Under the existing guidelines (USEPA 1986), chemicals are classified as either Group A, Group B1, Group B2, Group C, Group D, or Group E. Group A includes those substances for which high-quality studies have demonstrated a relationship between the exposure to the substance in question and the development of cancer in human populations. Groups B1, B2, and C represent chemicals with limited (B1) or insufficient (B2) human evidence of carcinogenicity, and sufficient (B1, B2) or insufficient (C) animal data. Group D substances are those for which there is

insufficient evidence or not evidence of carcinogenicity in humans or animals and Group E substances are those not having evidence of carcinogenicity available in adequate human or animal studies.

6.3.1.2 Reference Doses and Reference Concentrations

Toxicity criteria for non-carcinogens are generally developed using verified risk reference doses (RfDs) and reference concentrations (RfCs). These are developed by USEPA and listed in IRIS or can be obtained from HEAST (USEPA 1997b) and supplements. RfDs are expressed in units of dose (mg chemical/kg body weight-day) and are usually derived either from human studies involving workplace exposures or from animal studies. In addition, RfDs are estimates (with uncertainty spanning perhaps an order of magnitude) of the daily exposure to the human population (including sensitive subpopulations) that is likely to be without an appreciable risk of deleterious effects during a lifetime. The RfD is used as a reference point for gauging the potential effects of exposures. Usually, exposures (as chemical intakes or doses) that are less than the RfD are not likely to be associated with adverse health effects.

RfDs are developed for both chronic and sub-chronic exposures. Chronic RfDs are presented in IRIS or HEAST and are intended for use in evaluating exposures of durations greater than seven years. Sub-chronic RfDs are developed by USEPA's NCEA and are used to characterize the potential for the occurrence of non-carcinogenic effects associated with short-term exposures [two weeks to seven years as defined by USEPA (1989)]. The sub-chronic RfDs are developed similarly to chronic RfDs and are typically equal to chronic RfDs or are an order of magnitude greater (less stringent). Sub-chronic RfDs are presented in HEAST but are no longer being reviewed and updated in the same manner as IRIS. Because there is greater uncertainty associated with the sub-chronic RfDs, chronic RfDs have been used in this HHRA.

RfDs are derived using uncertainty factors that reflect scientific judgment regarding the various types of data used to estimate the RfD. RfDs are typically estimated from no observable adverse effect levels (NOAELs) or lowest observable adverse effect levels (LOAELs) in human or animal studies. Uncertainty factors, generally 10-fold factors, are intended to account for:

- The variation in sensitivity among members of the human population;
- The uncertainty in extrapolating animal data to the case of humans;
- The uncertainty in extrapolating from data obtained in a study that is less-than-lifetime exposure;
- The uncertainty in using LOAEL data, when necessary, rather than NOAEL data; and
- The inability of a single study to adequately address every possible adverse outcome in humans.

To derive RfDs, NOAELs or LOAELs are divided by one or more uncertainty factors, as appropriate. When taken together, these uncertainty factors may confer an extra margin of safety of up to a factor of 10,000 below a LOAEL. In some cases, modifying factors are also applied to RfDs to take into account other uncertainties in the toxicity database and reflect the professional judgment of those reviewing the database. The net result is that RfDs are generally considered to provide a conservative estimate of the likelihood of adverse non-carcinogenic effects.

6.3.1.3 Adjustment for Dermal Absorption

Toxicity criteria have not been developed by USEPA specifically for dermal absorption; instead, oral toxicity criteria are adjusted to assess this pathway. In order to have a meaningful comparison between the dermal absorption dose estimates, which represent internal (or absorbed) doses, and oral toxicity criteria, which typically represent potential (or administered) doses, toxicity criteria are modified to represent absorbed doses. The method for modifying toxicity criteria involves calculation of an absolute oral absorption factor for each chemical and use of this value to increase the chemical's CSF or to decrease the chemical's RfD, as shown in the following equations:

- Adjusted Dermal CSF = CSF/Absolute oral absorption factor
- Adjusted Dermal RfD = RfD x Absolute oral absorption factor

The absolute oral absorption factors should reflect the specific conditions under which the toxicological study was conducted (e.g., method of administration such as gavage, water or diet, and vehicle of administration such as solvent or solution). The absolute oral absorption factors and adjusted toxicity criteria for the COPCs used when evaluating dermal absorption are presented in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q), Tables E.1-5.1 and E.1-6.1, Tables E.2-5.1 and E.2-6.1, and Tables E.3-5.1 and E.3-6.1, respectively. The adjusted CSFs and RfDs presented in these tables were used to evaluate potential risks associated with dermal absorption.

6.4 RISK CHARACTERIZATION

Quantitative risks and hazards due to exposure to COPCs are estimated and summarized by combining toxicity criteria (presented in the Toxicity Assessment) with CDIs (calculated in the Exposure Assessment). Methods used to calculate risks and hazards are taken from USEPA (1989).

For exposures to potential carcinogens, the individual upper-bound excess lifetime cancer risk was calculated by multiplying the estimated CDI by the CSF. In order to assess the individual excess lifetime cancer risks associated with simultaneous exposure to COPCs, the risks derived from the individual chemicals are summed within each exposure pathway. For the residential scenario, carcinogenic risk was evaluated for the lifetime resident.

Non-carcinogenic adverse health effects are calculated by dividing the CDI of each COPC by its RfD, forming a HQ. HQs greater than one (1) indicate the potential for adverse health effects. To estimate non-carcinogenic adverse health effects due to simultaneous exposure to several COPCs, HQs for individual COPCs are summed within each exposure pathway to form a Hazard Index (HI). As with HQs, HIs that are greater than 1 indicate potential adverse health effects. In such cases, COPCs are divided into categories based on the target organ affected (e.g., liver, kidney) and target organ-specific HIs are recalculated by summing HQs that effect the same target organ. The target organ analyses are presented in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q) in Tables E.1-9.1 through E.1-9.10, E.2-9.1 through E.2-9.10, and E.3-9.1 through E.3-9.10. Non-carcinogenic hazards were evaluated for both child and adult residents independently.

Excess lifetime cancer risks derived in this report are compared to USEPA's target risk range for Superfund sites of 1E-06 to 1E-04 (USEPA 1989). In addition, USEPA's Office of Solid Waste and Emergency Response has issued a directive (USEPA 1991) clarifying the role of HHRA in the Superfund process. The directive states that, if the cumulative carcinogenic risk to a receptor (based on reasonable maximum exposure for both current and future land use) is less than 1E-04 and the non-carcinogenic HI is equal to or less than 1, action generally is not warranted unless adverse environmental effects are likely.

Calculation of risks and hazards due to exposure to COPCs are presented in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q) in Tables E.1-7.1 through E.1-7.10, E.2-7.1 through E.2-7.10, and Tables E.3-7.1 through E.3-7.10, respectively. A refinement of the HIs based on target organs is conducted. As shown in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q) in Tables E.1-9.1 through E.1-9.10, E.2-9.1 through E.2-9.10, and E.3-9.1 through E.3-9.10, the refinement consists of calculating HIs on a target organ-specific basis. In addition in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q), Tables E.1-10.1 through E.1-10.3, E.2-10.1 through E.2-10.2, and E.3-10.1 through E.3-10.3 summarize risks and hazards for risk/HI drivers (i.e., those COPCs contributing to a total risk greater than 1.E-04 or a total target organ hazard greater than 1).

Risks and hazards presented in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q) in Tables E.1-9.1 through E.1-9.10, E.2-9.1 through E.2-9.10, and Tables E.3-9.1 through E.3-9.10 are summarized in the tables below.

SWMU 35 – Summary of Risks and Hazards

Timeframe/Receptor	Risk	HI	Risk Drivers	Target Organ Segregation HI>1
Current/Future Maintenance Worker (Surface Soil)	1.E-06	0.1	None	None

6.4.1 Lead Exposure Model

The mean concentrations for lead in surface soil and total soil for SWMU 35 (233.6 mg/kg - surface soil and 137.1 mg/kg - total soil), SWMU 37 (121 mg/kg - surface soil and 64.05 mg/kg - total soil), and SWMU 38/AOC Q (26.61 mg/kg - surface soil and 17.63 mg/kg - total soil) were below the residential lead screening level of 400 mg/kg; therefore, additional lead modeling was not conducted for the sites.

6.4.2 Iron Margin of Exposure Evaluation

Because iron concentrations in soil resulted in an HQ of 0.5 or higher for the hypothetical future child resident at the sites, a "margin of exposure evaluation" was conducted for the sites. This evaluation consists of a comparison of estimated intake of iron to the RDA and concentrations known to cause adverse health effects in children (USEPA 2001a).

For the margin of exposure evaluation, the estimated iron intakes at the sites for a hypothetical future resident child scenario for surface soil and total soil are calculated using the assumptions and equations provided in Appendices E.1, E.2, and E.3 for SWMU 35, SWMU 37, and SWMU 38/AOC Q, respectively. These estimated iron intake levels are then compared to the RDA for children (6 months to 10 years old) of 10 mg/day (NCEA 1996). In addition, using an average child weight of 15 kilograms (USEPA 1989), the child intakes for surface soil and total soil are calculated and compared to the calculated provisional (risk reference dose) RfD of 0.7 mg/kg-day. The results of the margin of exposure evaluation are summarized in the table below.

Results of Iron Margin of Exposure Evaluation

		RDA Evaluation			Provisional Risk Reference Dose (RfD) Evaluation		
	Iron EPC (mg/kg)	Child Daily Intake Estimate (mg/day)	RDA (mg/day)	Result	Child Daily Intake (mg/kg-day)	Calculated Provisional RfD (mg/kg-day)	Result
SWMU 35	25,518	4.9	10	<RDA	0.33	0.7	<RfD
SWMU 37	25,458	4.9	10	<RDA	0.33	0.7	<RfD
SWMU 38/ AOC Q	26,000	5.0	10	<RDA	0.33	0.7	<RfD

The iron exposure assessment results for the hypothetical future child resident were below the applicable iron margin of exposure screening criteria for SWMU 35, SWMU 37, and SWMU 38/AOC Q.

6.4.3 Background

Statistical evaluations were conducted to compare metals concentrations in soil at the sites to background concentrations presented in the RFAAP Facility-Wide Background Study Report (IT 2001). These evaluations followed the procedures outlined in the USEPA *Guidance for Comparing Background and Chemical Concentrations in Soil for CERCLA Sites* (USEPA 2002a) and included distribution testing and comparisons of site data to background using ProUCL 4.0 (USEPA 2007b). At the sites, if the distribution testing showed that either site data sets and background data sets in each case were not normal, consistent with Section 4.1 of the above referenced USEPA guidance, comparisons of site to background were conducted using non-parametric testing to evaluate whether site concentrations were consistently higher or lower than the background data set. If the distribution of the site and background data sets were both distributed normally, a paired t-test was conducted to evaluate whether site concentrations were consistently higher or lower than the background data set unless non-detects are present in either data set then the default comparison using ProUCL 4.0 is nonparametric. Appendix D presents results of the statistical evaluations and a summary of the results is presented in the following table.

Summary of Statistical Background Evaluations for Metals

Exposure Medium	Test Result Above Background?	SWMU 35	SWMU 37*	SWMU 38/AOC Q
Surface Soil	**Yes**	Al and Cr	Al and Cr	Al
	No	As, Co, Fe, Mn, and V	As, Co, Fe, Mn, and V	As, Cr, Co, Fe, Mn, and V
Total Soil	**Yes**	Al and Cr	Al and Cr	Al and Mn
	No	As, Co, Fe, Mn, and V	As, Co, Fe, Mn, and V	As, Cr, Co, Fe, and V

Notes: * Background evaluation was not conducted for mercury (SWMU 37 surface soil) due to the number of detection in the background data set. Al = aluminum, As = arsenic, Co = cobalt, Cr = chromium, Fe = iron, Mn = manganese, and V = vanadium.

As indicated by the results, aluminum concentrations are above background for both surface soil and total soil at all three sites. Chromium concentrations are above background for both surface soil and total soil at SWMUs 35 and 37. Manganese concentrations are above background for total soil at SWMU 38/AOC Q.

6.5 HHRA SUMMARY

This HHRA was performed to evaluate the potential human health effects associated with previous activities at the three sites. Receptors evaluated for both areas included: current/future maintenance worker, hypothetical future construction worker, hypothetical future commercial worker, hypothetical future adult resident, hypothetical future child resident, and hypothetical future lifetime resident.

6.5.1 SWMU 35 Summary

As presented in Section 6.4, the total risk for each receptor is below or within USEPA's target risk range for Superfund sites (1E-06 to 1E-04, USEPA 1989). The total HIs after target organ segregation for all receptors except the hypothetical future construction worker (CNS) and hypothetical future child resident (GI tract, liver, and vascular) are equal to or below the USEPA reference HI of 1. The iron exposure assessment results for the hypothetical future child resident were below the applicable iron margin of exposure screening criteria for SWMU 35. Lead modeling was not conducted for the site due to mean concentrations of lead in surface and total soil below the residential screening level.

Hypothetical Future Construction Worker

The site-related CNS HI for the hypothetical construction worker, when excluding the metal hazard driver in total soil detected below background (manganese), is 2 due to inhalation of aluminum in total soil. Since the HI greater than 1 is due to aluminum at the site, an additional background comparison of site concentrations to its background point estimate (UTL) was conducted for the site to assess whether site soil concentrations for aluminum were significantly above background. UTLs have been used at RFAAP to evaluate whether there is statistically significant evidence of concentrations consistently higher than background at a site. In cases where calculated target risks or hazards for a metal are above the USEPA recommended ranges, the UTLs also have been used at RFAAP as a remedial goal when UTLs are above risk-based calculated remedial goals. Detected site concentrations for aluminum are below its UTL; and therefore, aluminum concentrations at the site are not considered above the range of facility background. Thus, when considering background the site-related CNS HI for the construction worker would be less than 1.

Hypothetical Future Child Resident (Surface Soil and Groundwater)

The site-related GI tract and liver HIs for the hypothetical future child resident, when excluding the metal hazard driver detected below background (iron) in surface soil, are 1 due to chromium in surface soil.

The site-related vascular HI for the hypothetical future child resident, when excluding the metal hazard driver detected below background (arsenic) in surface soil, rounds to 1 due to nitroglycerin in surface soil. In addition, note that nitroglycerin was detected in 1 of 22 soil samples.

Hypothetical Future Child Resident (Total Soil and Groundwater)

The site-related vascular HI for the hypothetical future child resident, when excluding the metal hazard driver detected below background (arsenic) in total soil, rounds to 1 due to nitroglycerin in total soil. In addition, note that nitroglycerin was detected in 1 of 22 soil samples.

6.5.2 SWMU 37 Summary

As presented in Section 6.4, the total risk for each receptor is below or within USEPA's target risk range for Superfund sites (1E-06 to 1E-04, USEPA 1989). The total HIs after target organ segregation for all receptors except the hypothetical future construction worker (CNS) and hypothetical future child resident (CNS, GI tract, and liver) are equal to or below the USEPA reference HI of 1. The iron exposure assessment results for the hypothetical future child resident were below the applicable iron margin of exposure screening criteria for SWMU 37. Lead modeling was not conducted for the site due to mean concentrations of lead in surface and total soil below the residential screening level.

Hypothetical Future Construction Worker

The site-related CNS HI for the hypothetical construction worker, when excluding the metal hazard driver detected below background (manganese) in total soil, is 3 due to inhalation of aluminum in total soil. Since the HI greater than 1 is due to aluminum at the site, an additional background comparison of site concentrations to its background point estimate (UTL) was conducted for the site to assess whether site soil concentrations for aluminum were significantly above background. UTLs have been used at RFAAP to evaluate whether there is statistically significant evidence of concentrations consistently higher than background at a site. In cases where calculated target risks or hazards for a metal are above the USEPA recommended ranges, the UTLs also have been used at RFAAP as a remedial goal when UTLs are above risk-based calculated remedial goals. Detected site concentrations for aluminum are below its UTL; and therefore, aluminum concentrations at the site are not considered above the range of facility background. Thus, when considering background the site-related CNS HI for the construction worker would be less than 1.

Hypothetical Future Child Resident (Surface Soil and Groundwater)

The site-related CNS HI for the hypothetical future child resident, when excluding the metal hazard driver detected below background (manganese) in surface soil, rounds to 1 due to aluminum in surface soil and manganese in groundwater.

The site-related GI tract HI for the hypothetical future child resident, when excluding the metal hazard driver detected below background (iron) in surface soil, is 1 due to chromium in surface soil.

The liver HI for the hypothetical future child resident, when excluding the metal hazard driver detected below background (iron) in surface soil, is 2 due to chromium in surface soil and heptachlor epoxide in groundwater. The heptachlor epoxide detection was below its MCL. Data suggests the site is not the source of pesticides in groundwater since the pesticides detected in groundwater were not detected in soil at the site and pesticides were also detected in background well 37MW1. Therefore, the site related liver HI for the hypothetical future child resident is 1 due to chromium in surface soil.

Hypothetical Future Child Resident (Total Soil and Groundwater)

The site-related CNS HI for the hypothetical future child resident, when excluding the metal hazard driver detected below background (manganese) in total soil, rounds to 1 due to aluminum in total soil and manganese in groundwater.

The site-related GI tract HI for the hypothetical future child resident, when excluding the metal hazard driver detected below background (iron) in total soil, is 1 due to chromium in surface soil.

The liver HI for the hypothetical future child resident, when excluding the metal hazard driver detected below background (iron) in total soil, is 2 due to chromium in total soil and heptachlor epoxide in groundwater. The heptachlor epoxide detection was below its MCL. Data suggests the site is not the source of pesticides in groundwater since the pesticides detected in groundwater were not detected in soil at the site and pesticides were also detected in background well 37MW1. Therefore, the site related liver HI for the hypothetical future child resident is 1 due to chromium in total soil.

6.5.3 SWMU 38/AOC Q Summary

As presented in Section 6.4, the total risk for each receptor is below or within USEPA's target risk range for Superfund sites (1E-06 to 1E-04, USEPA 1989). The total HIs after target organ segregation for all receptors except the hypothetical future construction worker (CNS), hypothetical adult resident (CNS), and hypothetical future child resident (CNS) are equal to or below the USEPA reference HI of 1E+00. The iron exposure assessment results for the hypothetical future child resident were below the applicable iron margin of exposure screening criteria for SWMU 38/AOC Q. Lead modeling was not conducted for the site due to mean concentrations of lead in surface and total soil below than the residential screening level.

Hypothetical Future Construction Worker

The site-related CNS HI for the hypothetical construction worker is 6E+00 primarily due to inhalation of aluminum and manganese in total soil. Site aluminum and manganese concentrations in total soil were above background concentrations based on background comparisons for total soil. Since the HI greater than 1 is due to aluminum and manganese at the site, an additional background comparison of site concentrations to their background point estimates (UTLs) was conducted for the site to assess whether site soil concentrations for aluminum and manganese were significantly above background. UTLs have been used at RFAAP to evaluate whether there is statistically significant evidence of concentrations consistently higher than background at a site. In cases where calculated target risks or hazards for a metal are above the USEPA recommended ranges, the UTLs also have been used at RFAAP as a remedial goal when UTLs are above risk-based calculated remedial goals. Detected site concentrations for aluminum and manganese are below their UTLs; and therefore, aluminum and manganese concentrations at the site are not considered above the range of facility background. Thus, when considering background the site-related CNS HI for the construction worker would be less than 1.

Hypothetical Future Adult Resident

The site-related CNS HI for the hypothetical future adult resident is 2E+00 due to ingestion and dermal contact with manganese in groundwater.

Hypothetical Future Child Resident (Surface Soil and Groundwater)

The CNS HI for the hypothetical future child resident is 5E+00 due primarily to ingestion and dermal contact with manganese in groundwater (HI=4E+00) and ingestion and dermal contact with aluminum (HI=0.3) and manganese (HI=0.5) in surface soil. Manganese concentrations were below background in surface soil. The dissolved manganese detection in groundwater resulting in an HI of 4 is not considered site related given that, as previously discussed in Section 4.7.3, a site-specific source related to disposal activities for the dissolved manganese concentrations detected in well 38MW3 was not identified. In addition, the occurrence of dissolved manganese at concentrations above the T-RBC at one well location

38MW3 may be due natural geologic conditions (i.e., weathering of bedrock containing manganese and alluvial deposition). Therefore, the site-related CNS HI is 0.3 due to aluminum in surface soil.

Hypothetical Future Child Resident (Total Soil and Groundwater)

The CNS HI for the hypothetical future child resident is 5E+00 due primarily to ingestion and dermal contact with manganese in groundwater (HI=4E+00) and ingestion and dermal contact with aluminum (HI=0.2) and manganese (HI=0.5) in total soil. The dissolved manganese detection in groundwater resulting in an HI of 4 is not considered site related given that, as previously discussed in Section 4.7.3, a site-specific source related to disposal activities for the dissolved manganese concentrations detected in well 38MW3 was not identified. In addition, the occurrence of dissolved manganese at concentrations above the T-RBC at one well location 38MW3 may be due natural geologic conditions (i.e., weathering of bedrock containing manganese and alluvial deposition). Therefore, the site-related CNS HI is 0.7 due to aluminum and manganese in total soil.

6.6 UNCERTAINTIES

Risk assessments involve the use of assumptions, judgments, and incomplete data to varying degrees that contribute to the uncertainty of the final estimates of risk. Uncertainties result both from the use of assumptions or models in lieu of actual data and from the error inherent in the estimation of risk related parameters and may cause risk to be overestimated or underestimated. Based on the uncertainties described below, this risk assessment should not be construed as presenting an absolute estimate of risk to persons potentially exposed to COPCs.

Consideration of the uncertainty attached to various aspects of the risk assessment allows better interpretation of the risk assessment results and understanding of the potential adverse effects on human health. In general, the primary sources of uncertainty are associated with environmental sampling and analysis, selection of chemicals for evaluation, toxicological data, and exposure assessment. The effects of these uncertainties on the risk estimates are discussed below.

6.6.1 Environmental Sampling and Analysis

If the samples do not adequately represent media at the sites, hazard/risk estimates could be overestimated or underestimated. The sampling and analysis plan was designed to investigate anticipated areas of contamination and delineate area(s) of concern at the SWMUs. Therefore, there is less chance that the hazard/risk estimates are biased low. Also, if the analytical methods used do not apply to some chemicals that are present at each area, risk could be underestimated. Because the analytical methods at the site were selected to address all chemicals that are known or suspected to be present on the basis of the history of each area, the potential for not identifying a COPC is reduced.

Uncertainty in environmental chemical analysis can stem from several sources including errors inherent in the sampling or analytical procedures. Analytical accuracy errors or sampling errors can result in rejection of data, which decreases the available data for use in the HHRA, or in the qualification of data, which increases the uncertainty in the detected chemical concentrations. There is uncertainty associated with chemicals reported in samples at concentrations below the method reporting limit but still included in data analysis and with those chemicals qualified "J" indicating that the concentrations are estimated. Another issue involves the amount of blank related (i.e., B-qualified) data in the data set. These data were retained in the HHRA without modification. The inclusion of "B" qualified data in the risk assessment may overestimate risk.

6.6.2 Selection of Chemicals for Evaluation

A comparison of maximum detected chemical concentrations to USEPA Region III RBCs was conducted for both surface and total soil. Chemicals whose maximum concentrations were below their respective RBCs were not carried through the assessment. It is unlikely that this risk based screening excluded chemicals that should be included, based on the conservative exposure assumptions and conservatively

derived toxicity criteria that are the basis of the RBCs. Although following this methodology does not provide a quantitative risk estimate for every chemical, it focuses the assessment on the chemicals accounting for the greatest risks (i.e., chemicals whose maximum concentrations exceed their respective RBCs) and the cumulative risk estimates would not be expected to be significantly greater. As presented on the non-detect method detection limit (MDL) screening tables in Appendices E.1 (SWMU 35), Tables E.1-2.3 and E.1-2.5, E.2 (SWMU 37), Tables E.2-2.3 and E.2-2.5, and E.3 (SWMU 38/AOC Q), Tables E.3-2.3 and E.3-2.5, the maximum MDL exceeded the adjusted RBCs for several chemical in soil and groundwater; therefore, the site-related risks and hazards could be underestimated for the risk assessments due to inadequate detection limits.

Background concentrations of metals in soil at RFAAP have been characterized and are used in statistical comparisons to site soil to evaluate whether concentrations of metals detected at the sites are consistently higher or lower than background. Uncertainties associated with the use of these data may lead to a low-to-moderate overestimation or underestimation of surface and total soil risks due to metals.

Screening criteria are derived from RDAs for essential human dietary minerals, trace elements, and electrolytes that are toxic at very high doses (i.e., calcium, magnesium, potassium, and sodium). Omitting these essential human nutrients from further evaluation is expected to have a low effect on risk and hazard estimates.

The use of the October 2007 RBCs rather than the April 2009 Regional Screening Level Table for the SSP human health risk screening could result in the inclusion or exclusion of chemicals based on outdated toxicity data. Therefore to lessen the uncertainty associated with the use of these screening levels, an assessment of the data was conducted with respect to the April 2009 Regional Screening Levels which did not result in the identification of any additional COPCs for the sites.

6.6.3 Exposure Assessment

The primary areas of uncertainty affecting exposure parameter estimation involve the assumptions regarding exposure pathways, the estimation of exposure point concentrations, and the exposure parameters used to estimate chemical doses.

An underlying assumption in the HHRA is that individuals at the site would engage in activities that result in exposures via each selected pathway. For example, it was assumed that maintenance workers engage in regular activities (once a week) under current and future land use conditions resulting in exposure to COPCs. This assumption is conservative, in that it is more likely that the activity patterns occur occasionally.

In establishing EPCs, the concentrations of chemicals in the media evaluated are assumed to remain constant over time. Depending on the properties of the chemical and the media in which it was detected, this assumption could over estimate risks, depending on the degree of chemical transport to other media or the rate and extent a chemical degrades over time.

When calculating EPCs from sample data, one half of the MDL was sometimes used for non-detect samples in the calculation of the 95% UCL of the mean. Approaches which substitutes values for non-detected chemical concentrations are associated with uncertainty, because chemicals that were not detected at the specified sample MDL may be absent from the medium or may be present at a concentration below the sample MDL. The uncertainty of the exposure point concentration will increase as the number of non-detects in a data set increases and the uncertainty could result in either the overestimation or underestimation of EPCs.

The exposure parameters used to describe the extent, frequency, and duration of exposure is associated with uncertainty. Actual risks for individuals within an exposed population may differ from those predicted, depending upon their actual intake rates (e.g., soil ingestion rates), nutritional status, or body weight. Exposure assumptions were selected to produce an upper bound estimate of exposure in

accordance with USEPA guidelines regarding evaluation of potential exposures at Superfund sites (e.g., exposures were assumed to occur for 25 years for workers). In addition, many USEPA (1991) default exposure parameters are highly conservative and are based on risk management interpretations of limited data. For example, although current USEPA guidance recommends default soil ingestion rates of 100 mg/day for individuals over 6 years of age, other studies, such as Calabrese et al. (1990), have shown that the USEPA default soil ingestion rate of 100 mg/day is likely to greatly overestimate adult exposures and risks. In addition, chemicals in soil are assumed 100% bioavailable; this assumes that ingested chemicals present in a soil matrix are absorbed through the gastrointestinal (GI) tract, which is unlikely due to the affinity of contaminants for soil particles. Therefore, based on the conservative exposure assumptions used in the HHRA, exposures and estimated potential risks are likely to be overestimated for the ingestion of soil pathways.

Evaluation of the dermal absorption exposure pathway is affected by uncertainties in dermal exposure parameters. For example, there is uncertainty associated with the exposed skin surface areas used, since the choice of exposed body parts could slightly overestimate or underestimate risks. Uncertainties that are more significant are associated with the selection and use of dermal absorption factors. For this HHRA, the dermal absorption factors and calculations were based on USEPA Region III guidance, USEPA's *Risk Assessment Guidance for Superfund (RAGS): Part E, Supplemental Guidance for Dermal Risk Assessment* (USEPA 2004). Very limited information is available on dermal absorption of chemicals from contacted soil under environmental conditions. In fact, there are not actual human epidemiological data to support the hypothesis that absorption of soil bound compounds under exposure conditions is a complete route of exposure. For example, the Public Health Statements from the Agency for Toxic Substance Disease Registry (ATSDR 1999b) indicates cadmium is not known to result in human health effects by dermal absorption because virtually zero cadmium can enter the body through the skin under normal circumstances (i.e., without exposure to very high concentrations for long periods or exposure to skin that is damaged (ATSDR 1999a). Therefore, using the dermal absorption factors to evaluate dermal absorption exposures to soil may result in an overestimation of risks.

6.6.4 Toxicological Data

The HHRA relies on USEPA derived dose response criteria. These health effects criteria are conservative and are designed to be protective of sensitive subpopulations. The health criteria used to evaluate long-term exposures, such as RfDs or CSFs, are based on concepts and assumptions that bias an evaluation in the direction of overestimation of health risk. As USEPA notes in its *Guidelines for Carcinogenic Risk Assessment* (USEPA 1986), there are major uncertainties in extrapolating both from animals to humans and from high to low doses. There are important species differences in uptake, metabolism, and organ distribution of carcinogens, as well as species and strain differences in target site susceptibility, human populations are variable with respect to genetic constitution, diet, occupational and home environment, activity patterns, and other cultural factors.

These uncertainties are compensated for using upper bound 95% UCLs for CSFs (carcinogens), and safety factors for RfDs (non-carcinogens). The assumptions used here provide a rough but plausible estimate of the upper limit of risk; in other words, it is not likely that the true risk would be much more than the estimated risk, but it could very well be considerably lower. More refined modeling in the area of dose response calculation (e.g., using maximum likelihood dose response values rather than the 95% UCL) would be expected to substantially lower the final risk.

For dermal absorption exposure pathways, the absence of dermal toxicity criteria necessitates the use of oral toxicity data. To calculate risk estimates for the dermal absorption pathway, absorbed dermal absorption doses are combined with oral toxicity values (also discussed above in Section 6.3). Oral toxicity values, which are typically expressed in terms of potential (or administered) doses, should be adjusted when assessing dermal absorption doses, which are expressed as internal (or absorbed) doses. In this assessment, absolute oral absorption factors that reflect the toxicity study conditions were used to

modify the oral toxicity criteria. For those chemicals lacking sufficient information, a default oral absorption factor of 1.0 was used. The risk estimates for the dermal absorption pathways may be overestimated or underestimated, depending on how the values used in the HHRA reflect the difference between the oral and dermal routes.

Inhalation toxicity criteria are unavailable for many of the COPCs. This HHRA does not use oral-based toxicity criteria to estimate risks from inhalation exposure because of the following uncertainties associated with such a substitution:

- Many contaminants show portal-of-entry toxicity – that is, adverse health effects occur primarily at the tissue site at which the chemical is introduced into the body (e.g., GI tract, lung, or skin). For example, orally administered benzo(a)pyrene is associated with benign and malignant tumors in the gut mucosa (Neal and Rigdon 1967), but inhaled benzo(a)pyrene produces an increased incidence of upper respiratory tract tumors (Thyssen et al. 1981). Therefore, quantitative risk estimates based on these two administration routes are dissimilar;
- Physiological and anatomical differences between the GI tract and respiratory systems invalidate a cross-route quantitative risk extrapolation. The small intestine of humans contains a very large surface area that readily absorbs most compounds by passive diffusion (Klaasen et al. 1986). The oral absorption of a few compounds, such as iron, is an energy-dependent (active-transport) process, wherein; the absorption rate is proportional to the body's current need for iron;
- The rate and extent of pulmonary absorption are much more complex and depend on such factors as particle size distribution of the airborne toxicant and blood-gas solubility of the toxicant (Klaasen et al. 1986). Particles with median aerodynamic diameters of approximately 1 micrometer (μm) or less are absorbed by the alveolar region of the human lung. Larger particles deposit in the tracheobronchial or nasopharyngeal regions where they are cleared by mucociliary mechanisms and subsequently swallowed or physically removed and exhaled. Therefore, pulmonary absorption is more highly dependent on the physiochemical properties of the material than oral absorption;
- Because highly soluble gases (e.g., chloroform) are more rapidly absorbed into the blood than poorly soluble gases (e.g., ethylene), they take much longer to reach equilibrium. Thus, the inhalation absorption rate of a gas is more dependent on blood solubility than the oral absorption rate of the same substance administered as a liquid; and
- Human inhalation risk estimates based on oral toxicity data in subhuman species are distorted by both route-to-route extrapolation and interspecies extrapolation. For example, the rodent GI tract, which includes a structurally unique fore stomach, is anatomically and functionally distinct from the human lung, which contains a very large alveolar surface area for extensive absorption. The rate and extent of absorption across these distinct physiological systems are not alike.

In addition, for inhalation exposure to substances present as dusts, vapors, gases, or airborne particulate matter, dose extrapolation is far more complex, and therefore associated with uncertainty. The major confounding factors that prohibit a direct dose extrapolation of an inhaled toxicant are the following:

- Over 40 functionally different cell types in the lung – the distribution, consequent metabolic reactions, and air exchange rates vary widely across species;
- Differential concentration and activity of the detoxifying protein glutathione;
- Interspecies and intraspecies differences in the ability to repair pulmonary cell damage, and to clear toxic contaminants and immune complexes from the respiratory tract. For example, species vary in the ability to activate macrophages – nonspecific immune cells that can both protect the inner lining of the respiratory system and, at high concentrations, damage healthy tissues;

- Anatomical variations in the respiratory pathway, which affect both absorption rates and time to reach steady-state blood levels; and
- Sensitivity to solubility and concentration variables; because of metabolic saturation (i.e., the exhaustion of normal metabolic activity caused by exposure to high concentrations), highly soluble contaminants deviate from first-order kinetics – which makes it difficult to predict the rates and extent of biotransformation and detoxification reactions. Furthermore, intermittent inhalation exposure to highly blood-soluble chemicals results in bioaccumulation in fat tissue because of the insufficient time between exposure sessions for complete clearance of the contaminant. Such slow release from the fat compartment to other body tissues can result in toxicological and metabolic effects that are difficult to assess and vary across species.

For chemicals without IRIS toxicity criteria, provisional toxicity criteria were used where available (Appendices E.1, E.2, and E.3 - Tables E.1-5.1 through E.1-6.2, Tables E.2-5.1 through E.2.6-2, and Tables E.3-5.1 through E.3-6.2). Provisional toxicity criteria present a source of uncertainty, since USEPA has evaluated the compound, but consensus has not been established on the toxicity criteria. Provisional oral toxicity values were used for aluminum, arsenic, chromium, cobalt, iron, vanadium, Aroclor 1254, heptachlor epoxide, chloroform, and nitroglycerin. For this assessment, use of provisional toxicity criteria was preferable to not evaluating the chemical in order to limit data gaps. However, because these toxicity criteria have not been formally accepted by USEPA, there is uncertainty with these values and, therefore, with the risks calculated using these toxicity criteria.

Some detected constituents (cobalt, cyclohexane, methylcyclohexane, di-n-octylphthalate, and dimethylphthalate) do not have USEPA Region III RBCs. Due to the low detection frequency for cyclohexane, methylcyclohexane, di-n-octylphthalate, and dimethylphthalate, these chemicals were not carried forward as COPCs into the HHRA. Provisional/surrogate toxicity values were researched for cobalt and cancer risk/non-cancer hazard calculations were derived for cobalt. It is undetermined if the uncertainty is biased high or low for cobalt because of the provisional nature of the toxicity data used. However, cobalt is addressed quantitatively in the HHRA using available toxicity data to reduce the level of uncertainty associated with the risk assessment results.

6.6.5 Risk Characterization

Minor uncertainty is associated with rounding of the risk and hazard estimates. Thus, the actual risk or hazard may be slightly greater or less than the presented values. A related issue is that rounding causes minor differences between summed risk and hazard values, depending on how the summing is performed. For example, RAGS Table 7s in Appendices E.1 (SWMU 35), E.2 (SWMU 37), and E.3 (SWMU 38/AOC Q) presents risks and hazards that are summed for exposure route, exposure point, exposure medium, and medium total. Only for the first (exposure route) are the individual chemical-specific risks and hazards summed to derive the total. For the subsequent summations (exposure point, exposure medium, and medium total), each is the summation of the preceding sums. For this reason, there can also be minor rounding-related differences between the 'same' values presented in RAGS Table 9s and 10s in Appendix E.

6.7 HHRA CONCLUSIONS

This HHRA was performed to evaluate the potential human health effects associated with previous activities at the SWMUs Receptors evaluated for both areas included: current/future maintenance worker, hypothetical future construction worker, hypothetical future commercial worker, hypothetical future adult resident, hypothetical future child resident, and hypothetical future lifetime resident.

6.7.1 SWMU 35 HHRA Conclusions

In summary for SWMU 35, the results of the risk assessment indicate that the calculated site-related cancer risks and hazards are within USEPA target ranges for each of the receptors evaluated when

considering background, target organs, and frequency of detection, and site-specific conditions, with the exception of the CNS HI for the hypothetical construction worker of 2 primarily due to inhalation of aluminum in total soil. Based on background point estimate comparison, aluminum concentrations at the site were not considered significantly above background at the site. The results of the human health risk assessment did not indicate a requirement for further action for the site.

6.7.2 SWMU 37 HHRA Conclusions

In summary for SWMU 37, the results of the risk assessment indicate that the calculated site-related cancer risks and hazards are within USEPA target ranges for each of the receptors evaluated when considering background, target organs, and frequency of detection, and site-specific conditions, with the exception of the CNS HI for the hypothetical construction worker of 3 primarily due to inhalation of aluminum in total soil. Based on background point estimate comparison, aluminum concentrations at the site were not considered significantly above background at the site. The results of the human health risk assessment did not indicate a requirement for further action for the site.

6.7.3 SWMU 38/AOC Q HHRA Conclusions

In summary for SWMU 38/AOC Q, the results of the risk assessment indicate that the calculated site-related cancer risks and hazards are within USEPA target ranges for each of the receptors evaluated when considering background, target organs, frequency of detection, and site-specific conditions, with the exception of the CNS HI for the hypothetical construction worker of 6 primarily due to inhalation of aluminum and manganese from total soil. Based on background point estimate comparisons, aluminum and manganese concentrations at the site were not considered significantly above background at the site. The results of the human health risk assessment did not indicate a requirement for further action for the site.

7.0 SCREENING LEVEL ECOLOGICAL RISK ASSESSMENT

7.1 ECOLOGICAL RISK SCREENING PROCESS

The purpose of the ecological risk screening is to provide conclusions and recommendations regarding potential ecological risk associated with SWMU 35, SWMU 37, and SWMU 38/AOC Q. SLERAs were performed in accordance with the Final Process for Ecological Risk Assessment – Radford AAP (URS 2007b). The SLERA process is summarized below in Sections 7.1.1 through 7.1.7. Refer to Appendix F.1 for a detailed description of the SLERA process utilized for the site evaluations and an example calculation. A summary of the SLERA results are provided in Section 7.2 (SWMU 35), Section 7.3 (SWMU 37), and Section 7.4 (SWMU 38/AOC Q) and the complete tables for the SLERAs are provided in Appendices F.2 (SWMU 35), F.3 (SWMU 37), and F.4 (SWMU 38/AOC Q).

7.1.1 Scope of Work

The SLERA includes Steps 1, 2, and 3a of the Ecological Risk Assessment Guidance for Superfund (ERAGS) (USEPA 1997). Step 1 includes a screening-level problem formulation and ecological effects evaluation. Step 2 includes a preliminary exposure estimate and risk calculation. Step 3a reviews and refines the conservative assumptions used in the risk calculation (Step 2). The addition of Step 3a focuses the outcome of the SLERA, streamlines the review process, and functions as the initial basis for ecological risk management decision making.

The objectives of the ecological risk screening are to:

- Identify potentially complete exposure pathways between COPECs and receptors;
- Assess whether the COPECs are above toxicological screening values that are considered to be protective of ecological receptors;
- Identify uncertainty and/or data gaps in the ecological risk screening; and
- Identify an appropriate SMDP for each site area based on the ecological risk screening results.

7.1.1.1 Ecological Site Characterization

An overview of the site physiography, water resources, geology, and soil for SWMUs 35, 37, 38, and AOC Q is presented in Section 2.0. SWMU 35 consists of a calcium sulfate disposal bed located in the northeastern section of the MMA approximately 120 feet from the New River. SWMUs 37, 38, and AOC Q consist of two calcium sulfate disposal beds (SWMU 37 and 38) and one calcium sulfate treatment and disposal area (AOC Q) located in the northwestern section of the MMA. Each unit is surrounded by an earthen berm and bordered by the New River approximately 300-400 ft to northwest and railway tracks and a gravel road to the east.

The sites are located in densely vegetated areas and dense woods surround SWMU 38 and AOC Q to the north, south, and west where the topography slopes downward towards the New River. Observations made during the site reconnaissance indicate the vegetation community at the sites appears healthy and vigorous (see photographic logs, Appendix A). Indications of chemical vegetative stress were not observed.

In addition to the information contained in Section 2.0, additional site characterization is required for the ecological risk screening, which includes local ecological receptors (threatened and endangered species) and ecological resources. A discussion of potential biota likely to use the site areas, are included in this section. During site visits, wildlife species were observed at the site such as squirrels, deer, and red foxes.

The Virginia Department of Conservation, Division of Natural Heritage and U.S. Fish and Wildlife Service were contacted to gather information regarding the potential for threatened or endangered species to utilize the RFAAP. Results of these inquiries are provided in Appendix F.5.

In addition, the Virginia Department of Game and Inland Fisheries Installation-Wide Biological Survey (1999) recorded various species associated with the grassland communities at RFAAP. Based on their survey of the grassland habitats, the invertebrates (approximately 250 species) and birds (83 species) accounted for the majority of species observations at RFAAP. Potential species utilizing the grassland areas of the site include common passerine birds (e.g., American robin) and small mammals (e.g., short-tailed shrew). Larger mammals (e.g., white-tailed deer and red fox) and raptors (e.g., red-tailed hawk) may potentially utilize the grassland habitat for foraging. Animals such as the mallard duck, belted kingfisher, and raccoon could be expected to forage in the New River.

The Virginia Department of Game and Inland Fisheries survey identified three threatened wildlife species and two rare plant species associated with RFAAP grassland communities (currently not on the 2002 Plant Watch List; http://www.dcr.state.va.us/dnh/plantlist02.pdf). They include:

- Regal Fritillary Butterfly (*Speyeria idalia*);
- Henslow's Sparrow (*Ammodramus henslowii*);
- Loggerhead Shrike (*Lanius ludovicianus*);
- Midland Sedge (*Carex mescochorea*); and
- Shaggy False Gromwell (*Onosmodium hispidissimum*).

Threatened wildlife observations in 1999 at RFAAP included the Regal Fritillary Butterfly (VDGIF 1999). The Regal Fritillary Butterfly was documented in the east-central and eastern edges of the MMA. No threatened wildlife species or rare plant species were identified at the sites.

7.1.2 Identification of Chemicals of Potential Ecological Concern

SWMUs 35 and 37 are evaluated independently in their SLERAs. SWMU 38 and AOC Q are evaluated together in their SLERA for soil given their close proximity and the use of AOC Q as a sludge drying bed when SWMU 38 was full.

7.1.2.1 Approach

Soil samples were collected from 0 to 1 ft bgs below organic layers at the surface. This layer contains the zone of highest biological activity of soil organisms and the soil that is most frequently contacted by terrestrial biota. Although fossorial wildlife may be in contact with soil below 1 ft bgs, the preys of these animals are primarily associated with surficial soil. Furthermore, incidental exposure to the soil below 1 ft bgs is likely to be insignificant relative to surface soil exposure.

Terrestrial grassland surficial soil (0 to 1 ft bgs) represents the potential exposure media to ecological receptors. The following sections describe the process used to evaluate soil, the selection of COPECs evaluated in the SLERA, and the uncertainties associated with COPEC selection.

7.1.2.1 Terrestrial

Potential ecological receptors at SWMUs 35, 37, 38, and AOC Q may be exposed to COPECs in soil through the following exposure routes:

- Direct contact/absorption from soil;
- Direct ingestion of soil;
- Incidental ingestion of soil; and
- Direct ingestion of biota with accumulated COPECs.

Although receptors may be exposed to COPECs through inhalation or drinking surface water, sufficient literature regarding toxicity due to these pathways is lacking to quantitatively evaluate such exposure

routes. Given the potential mobility of COPECs between food web trophic levels, a number of terrestrial categories were selected. Individual receptor species were selected to represent five wildlife receptor categories and these species possess the following characteristics that are essential for assessing COPEC mobility within the food web:

- Highly likely to occur at the site;
- Limited home range;
- Important role in the local food web; and
- Sufficient toxicological information is available in the literature.

Receptor categories and the species selected to represent the wildlife categories include:

- Plant communities;
- Soil invertebrate/microbial communities;
- Omnivorous birds: American Robin (*Turdus migratorius*);
- Carnivorous birds: Red-tailed Hawk (*Buteo jamaicensis*);
- Herbivorous animals: Meadow Vole (*Microtus pennsylvanicus*);
- Omnivorous mammals: Red Fox (*Vulpes vulpes*); and
- Carnivorous mammals: Short-tailed Shrew (*Blarina brevicauda*).

Potential wildlife utilizing the site includes passerine bird and small mammalian species common to RFAAP grasslands (VDGIF 1999).

7.1.3 Identification of Exposure Pathways and Potential Receptors Analysis

7.1.3.1 Data Organization

The following table identifies the soil samples used for the SLERA. These samples were selectively analyzed for TCL VOCs, TCL SVOCs, PAHs, explosives (including nitroglycerin and PETN), TCL pesticides, TCL PCBs, herbicides, TAL metals, and cyanide. Refer to Table 3-1 for a detailed list of samples and analytes.

Soil Samples Evaluated for SLERAs

Soil – SWMU 35		Soil – SWMU 37		Soil – SWMU 38/AOC Q	
35SB1A	35SB6A	37SB1A	37SB6A	38SB1A	38SB8A
35SB2A	35SB7A	37SB2A	37SB7A	38SB2A	38SB9A
35SB3A	35SB8A	37SB3A	37SB8A	38SB3A	38SB10A
35SB4A	35SB9A	37SB4A	37SB9A	38SB4A	QSB1A
35SB5A	35SB10A	37SB5A	37SB10A	38SB5A	QSB2A
				38SB6A	QSB3A
				38SB7A	QSB4A

Detected chemical occurrence and distribution tables for surface soil are presented in Tables F.2-1 for SWMU 35 (Appendix F.2), F.3-1 for SWMU 37 (Appendix F.3), and F.4-1 for SWMU 38/AOC Q (Appendix F.4). Refer to Section 4.0, Tables 4-1 (SWMU 35), 4-5 (SWMU 37), and 4-9 (SWMU 38/AOC Q) for a complete list of results for detected analytes. In addition, to evaluate the adequate sensitivity of the MDL for the necessary screening levels, Tables F.2-2 for SWMU 35 (Appendix F.2), F.3-2 for SWMU 37 (Appendix F.3), and F.4-2 for SWMU 38/AOC Q (Appendix F.4) provide a

screening of the maximum MDL versus available ecological screening values for non-detected chemicals in surface soil.

Chemicals that were not detected in at least one sample were considered as uncertain analytes in the evaluation of risk. Other qualified analytical data were retained in the assessment, with the exception of tentatively identified compounds (TICs) identified by the laboratory qualifier "NJ." TICs were not evaluated quantitatively in the risk assessment.

In cases where chemicals were analyzed using multiple laboratory methods, the analytical results for the method with the lowest MDL were retained for the risk assessment. For example, concentrations of explosives were assessed using Method 8330 rather than the SVOC Method 8270. Eliminating the method having the higher detection limit did not result in exclusion of samples with higher detected concentrations.

7.1.3.2 Ecological Conceptual Site Model (ECSM)

The terrestrial ECSM is presented on Figure 7-1. Surface soil is a potential exposure medium of concern based on historical activities at the site. Based on the site characterization and data, the terrestrial receptor exposure to surface soil pathway exists.

7.1.4 Identification of Assessment and Measurement Endpoints

Assessment endpoints are explicit statements of ecological resources (entities) and attributes of those entities that are important to protect (USEPA 1998). Measurement endpoints represent quantifiable ecological characteristics that can be measured, interpreted, and related to ecological resources chosen as assessment endpoints. Assessment and measurement endpoints for the resources in the terrestrial sites are outlined below.

7.1.4.1 Terrestrial

Assessment and measurement endpoints for terrestrial receptors are as follows:

Assessment Endpoints	Measurement Endpoints
• Survival, growth, and reproduction of terrestrial plants	• MDCs for chemicals detected in surface soil will be compared to concentrations representing no adverse effects thresholds to the survival of plants communities reported in the scientific literature
• Survival, growth, and reproduction of soil invertebrates and microbial communities	• MDCs for chemicals detected in surface soil will be compared to concentrations representing no adverse effects thresholds to the survival of soil invertebrates or microbial communities reported in the scientific literature
• Survival, growth, and reproduction of terrestrial wildlife (birds and mammals) populations and communities	• MDCs for detected bioaccumulative chemicals in soil will be compared to no observable adverse effects levels (NOAELs) and lowest observable adverse effects levels (LOAELs) associated with effects on growth, reproduction, or survival of terrestrial wildlife

7.1.5 Preliminary Exposure Estimate and Ecological Effects Evaluation

The preliminary exposure estimate and ecological effects evaluation considers the most conservative risk scenario. Highly conservative assumptions are used to estimate COPEC exposure to terrestrial receptors for pathways to be quantitatively evaluated. Conservative toxicity reference values (TRVs) are used to evaluate the ecological effects of exposure using the two approaches discussed below.

Risk is assessed by comparing the preliminary exposure estimate (MDC) of each detected chemical to the established TRV (detailed in Appendix F.1, Section 2.1). The preliminary risk is characterized in terms of a HQ, which is expressed as:

HQ = MDC/TRV

where:

HQ = Hazard Quotient for the constituent (unitless)
MDC = Maximum Detected Concentration for constituent (mg/kg)
TRV = Screening Level for constituent (mg/kg)

An HQ of less than one indicates that the contaminant alone is unlikely to cause adverse ecological effects. The potential for risk increases as the HQ increases above one. However, this result should be considered in the context of other characteristic of the exposure area. In addition, it should be noted that the calculation of chemical specific HQs does not account for multiple chemicals acting through the same exposure mechanism. The results of the preliminary exposure assessment are presented in Appendices F.2 (SWMU 35), F.3 (SWMU 37), and F.4 (SWMU 38/AOC Q).

7.1.5.1 Direct Contact Approach

The maximum soil concentrations for detected chemicals are used as the preliminary exposure estimate concentrations to develop a conservative risk scenario for the direct contact pathway to soil invertebrates and terrestrial plants.

7.1.5.2 Dose Rate Modeling Approach

Preliminary risk characterization for wildlife receptors uses the conservative preliminary exposure estimate and ecological effects evaluation to characterize risk to potential terrestrial receptors. Risk is assessed by comparing the preliminary exposure estimate of each detected bioaccumulative chemical, as defined in Table 4-2 in Bioaccumulative Testing and Interpretation for the Purpose of Sediment Quality Assessment, Status, and Needs, EPA-823-R-00-001, to the TRV developed in the ecological effects evaluation. An example calculation for dose rate modeling is provided in Appendix F.1, Section 4.1, utilizing the equation below.

$$C_{TRV} = \frac{ADD \cdot BW}{(IR_{food} \ (BAF_{food} \cdot DF) + IR_s \ )AF}$$

where:

C_{TRV} = NOAEL or LOAEL-based screening level (mg chemical/kg soil)

ADD = NOAEL or LOAEL (mg COPEC/kg body weight-day)

BW = Minimum Body Weight of the receptor (kg)

IR_{food} = Maximum Ingestion Rate of food (kg food ingested per day, dry weight)

BAF_{food} = BAF of most contaminated dietary component used, specific to prey type and COPEC (ratio of mg of COPEC/kg fauna, wet weight to mg COPEC/ kg substrate, dry weight)

DF = Dietary Fraction (most contaminated dietary component assumed to be 100% of diet)

IR_s = Maximum Incidental Ingestion Rate of soil (kg substrate ingested per day, dry weight)

AF = 100% Area Use Factor

In the preliminary dose rate modeling approach, the maximum COPEC concentrations for detected bioaccumulative chemicals, along with assumptions of maximum ingestion rate, minimum body weight, 100% area use, and 100% bioavailability are used in the conservative risk scenario as the preliminary exposure estimate for soil and compared to the calculated TRVs. Preliminary receptor-specific exposure parameters are presented on Table F.2-9 for SWMU 35 (Appendix F.2), Table F.3-9 for SWMU 37 (Appendix F.3), and Table F.4-9 for SWMU 38/AOC Q (Appendix F.4).

7.1.6 Refined Exposure Estimate and Risk Characterization

Refined exposure estimates and ecological effects are developed for two major receptor categories having complete exposure pathways to be quantitatively evaluated: 1) direct contact to plants and invertebrates, and 2) wildlife ingestion (i.e., omnivorous birds and mammals, carnivorous birds and mammals, and herbivorous mammals). The refined exposure and risk characterization, Step 3a of ERAGS, reviews and refines the conservative assumptions used in the risk calculation (USEPA 1997). In Step 3a, conservative assumptions used in the preliminary exposure and risk characterization are replaced with more environmentally realistic assumptions to evaluate risk posed by constituents identified in the preliminary risk characterization. The addition of Step 3a focuses the outcome of the SLERA, streamlines the review process, and functions as the initial basis for ecological risk management decision-making.

As noted below for the refined exposure estimate and risk characterization, the 95% UCL is used as the exposure concentration rather than the MDC. Methods used to calculate 95% UCLs are based on guidance provided in the following documents *Calculating Upper Confidence Limits for Exposure Point Concentrations at Hazardous Waste Sites* (USEPA 2002b) and *On the Computation of a 95% Upper Confidence Limit of the Unknown Population Mean Based Upon Data Sets with Below Detection Limit Observations* (USEPA 2006).

In general, the method used to calculate a 95% UCL depends on: 1) the number of samples, 2) the prevalence of non-detects, and 3) the data distribution (e.g., normal or lognormal). Non-detects introduce uncertainty in the data set because the true concentration may be between zero to just below the detection limit. Therefore, distributional assumptions are difficult to make for COPCs with a high rate of non-detects. ProUCL 4.0 (USEPA 2007b) is used to calculate EPCs for the sites. EPCs for soil COPECs are presented in Tables F.2-4 for SWMU 35 (Appendix F.2), F.3-4 for SWMU 37 (Appendix F.3), and F.4-4 for SWMU 38/AOC Q (Appendix F.4).

For the refined evaluation, risk is assessed by comparing the EPC (95% UCL) of each detected chemical to the TRV. The refined risk HQ is expressed as:

$$\mathbf{HQ = EPC/TRV}$$

where:

HQ = Hazard Quotient for the constituent (unitless)
EPC = Calculated Exposure Point Concentration for constituent (mg/kg)
TRV = Screening Level for constituent (mg/kg)

An HQ of less than 1 indicates no or negligible risk. The potential for risk increases as the HQ increases above unity. However, this result should be considered in the context of other characteristics of the exposure area. Results of the refined exposure assessment are presented in Appendices F.2 (SWMU 35), F.3 (SWMU 37), and F.4 (SWMU 38/AOC Q).

7.1.6.1 Direct Contact Approach

The refined exposure estimate for the direct contact pathway to soil invertebrate and microbial communities incorporates the 95% UCL as the exposure concentration for evaluating the COPECs using a conservative yet more realistic exposure assumption than MDCs.

7.1.6.2 Dose Rate Modeling Approach

The conservative assumptions used in the preliminary exposure estimate and ecological effects evaluation were replaced with more environmentally realistic assumptions resulting in a more realistic estimate of potential risk. An example calculation for dose rate modeling is provided in Appendix F.1, Section 4.4, utilizing the equation below.

$$C_{TRV} = \frac{ADD \cdot BW}{(IR_{food} \sum (BAF_{food} \cdot DF) + IR_s) AF_{refined}}$$

where:

C_{TRV} = NOAEL or LOAEL-based screening level (mg chemical/kg soil)

ADD = NOAEL or LOAEL (mg COPEC/kg body weight-day)

BW = Average Body Weight of the receptor (kg)

IR_{food} = Average Ingestion Rate of food (kg food ingested per day, dry weight)

BAF_{food} = BAF of dietary component used, specific to prey type and COPEC (ratio of mg of COPEC/kg fauna, wet weight to mg COPEC/ kg substrate, dry weight)

DF = Dietary Fraction

IR_s = Average Incidental Ingestion Rate of soil (kg substrate ingested per day, dry weight)

$AF_{refined}$ = Refined Area Use Factor (detailed below)

The refined exposure estimates and ecological effects are developed for wildlife receptors having complete exposure pathways to be quantitatively evaluated (i.e., omnivorous birds, and carnivorous and herbivorous mammals). In the refined model, an average body weight, average ingestion rate, and a 95% UCL as the EPC are used. Refined receptor-specific exposure parameters are presented on Tables F.2-9 for SWMU 35 (Appendix F.2), F.3-9 for SWMU 38 (Appendix F.3), and F.4-9 for SWMU 38/AOC Q (Appendix F.4). In addition, a realistic area use factor ($AF_{refined}$) was calculated as the ratio of the site area to the average home range of the receptor which is also presented in Tables F.2-9 for SWMU 35 (Appendix F.2), F.3-9 for SWMU 37 (Appendix F.3), F.4-9 for SMWU 38/AOC Q (Appendix F.4). Note that due to the proximity of SWMUs 37, 38, and AOC Q, an area use factor was calculated as the ratio of the sum of the site areas to the average home range of the receptor.

7.1.7 Risk Management – Scientific Management Decision Point

The findings of the ecological risk screen including site characterization and risk calculations are used as input to risk management decision-making for the site. The SMDP reached from the ecological risk screening concludes that one of the following statements is true:

- There is adequate information to conclude that ecological risks are negligible and therefore there is no need for further action at the site on the basis of ecological risk;
- The information is not adequate to make a decision at this point and further refinement of data is needed to augment the ecological risk screening; or
- The information collected and presented indicates that a more thorough assessment is warranted.

7.2 SLERA RESULTS – SWMU 35

7.2.1 Preliminary Risk Characterization

The complete preliminary risk characterization tables are provided in Appendix F.2 and summarized below.

7.2.1.1 Terrestrial Plants

Preliminary direct contact HQs calculated for plants are presented in Table F.2-6 for detected chemicals. Of the detected chemicals for which screening values were available, the concentrations of aluminum, calcium, chromium, copper, lead, manganese, mercury, nickel, vanadium, and zinc resulted in HQ values that were greater than 1.

7.2.1.2 Soil Invertebrates and Microbial Communities

Preliminary direct contact HQs calculated for invertebrates are presented in Table F.2-8 for detected chemicals. Of the detected chemicals for which screening values were available, the concentrations of chromium, copper, iron, manganese, mercury, vanadium, and zinc resulted in HQ values that were greater than 1.

7.2.1.3 Terrestrial Wildlife

Quantitative risk characterization for terrestrial wildlife is limited to direct ingestion of biota and incidental ingestion of soil. The preliminary risks for detected bioaccumulative chemicals are summarized in Table F.2-24 for each terrestrial wildlife receptor and the chemicals with HQs great than 1 are characterized as follows:

Receptor	NOAEL Only HQ>1	NOAEL and LOAEL HQ>1
Meadow Vole	cadmium, chromium, zinc, HMX, nitroglycerin	arsenic, copper, lead, selenium
Short-tailed Shrew	silver, cadmium	arsenic, chromium, copper, lead, zinc, Aroclor 1254, Aroclor 1260
Red Fox	nickel, selenium, silver, benzo(a)anthracene, HMX	arsenic, cadmium, chromium, copper, lead, zinc, Aroclor 1254, Aroclor 1260
American Robin	silver, 4,4'-DDT, Aroclor 1260, 2,4,6-TNT	cadmium, chromium, copper, lead, mercury, zinc, Aroclor 1254, 2,4-DNT
Red-tailed Hawk	chromium, zinc	lead

7.2.2 Refined Risk Characterization

The complete refined risk characterization tables are provided in Appendix F.2 and summarized below.

7.2.2.1 Terrestrial Plants

Refined direct contact HQs calculated for plants are presented in Table F.2-6 for detected chemicals. Of the detected chemicals for which screening values were available, the concentrations of aluminum, calcium, chromium, copper, lead, manganese, mercury, vanadium, and zinc resulted in refined HQ values that were greater than 1.

7.2.2.2 Soil Invertebrates and Microbial Communities

Refined direct contact HQs calculated for invertebrates are presented in Table F.2-8 for detected chemicals. Of the detected chemicals for which screening values were available, the concentrations of chromium, copper, iron, manganese, mercury, vanadium, and zinc resulted in refined HQ values that were greater than 1.

7.2.2.3 Terrestrial Wildlife

The refined risk characterization results are presented in Table F.2-24 and summarized below for each of the receptors with chemical HQs greater than 1:

Receptor	NOAEL Only HQ>1	NOAEL and LOAEL HQ>1
Meadow Vole	none	none
Short-tailed Shrew	Aroclor 1254 (2.5), Aroclor 1260 (2.4)	none
Red Fox	none	none
American Robin	chromium (1.3), lead (3.2)	none
Red-tailed Hawk	none	none

*Note: (2.5) = NOAEL-based HQ

7.2.3 Risk Management – Scientific Management Decision Point

Terrestrial plant COPECs with refined HQs greater than 1 included: aluminum, calcium, chromium, copper, lead, manganese, mercury, vanadium, and zinc. Although the refined aluminum HQ is greater than 1, the average pH in the soil is greater than 5.5 (see Appendix C.1). Therefore, since aluminum is biologically inactive in circumneutral to alkaline conditions (pH 5.5-8.0) such as those present at the site, aluminum is not considered a COPEC (USEPA 2003). Manganese and vanadium are consistently below background (see Appendix D, Table D.2-1a); therefore, these chemicals are not considered site-related. A discussion of the methodology of site versus background comparison is provided in Section 6.4.3. Even though the refined HQs for copper (1.5), lead (3.7), and zinc (1.1) are greater than 1 and concentrations at the site are above background concentrations via means comparison, these risks present low to negligible risk to plants at the site. The plant screening levels for calcium, chromium, and mercury are ORNL plant screening levels rather than ECO SSLs introducing uncertainty into the HQ calculations due to the uncertainty associated with these toxicity values. For example, the ORNL screening level is used for chromium, but during the development of ECO SSLs for chromium, it was determined that not enough data was available to derive an ECO SSL for plants; therefore, the data collected for the ORNL study was determined to be insufficient. In addition it is important to note that although metals concentrations in plants were above the screening levels, vegetation at the site is lush and diverse and indications of chemical vegetative stress were not observed with the exception of limited gravel areas as shown in site photographs (Appendix A). Soil invertebrates and microbial processes COPECs with refined HQs greater than 1 included chromium, copper, iron, manganese, mercury, vanadium, and zinc. Iron, manganese, and vanadium are consistently below background; therefore, these chemicals are not considered site-related. Even though the refined HQs for copper (1.3) and zinc (1.5) are slightly greater than 1 and concentrations at the site are above background concentrations via means comparison, these risks present low to negligible risk to soil invertebrates at the site. The invertebrate and microbial processes screening levels for chromium and mercury are ORNL earthworm screening levels rather than ECO SSLs introducing uncertainty into the HQ calculations due to the uncertainty associated with these toxicity values. For example, the ORNL screening level is used for chromium, but during the development of ECO SSLs for chromium, it was determined that not enough data was available to derive an ECO SSL for invertebrates; therefore, the data collected for the ORNL study was determined to be insufficient.

The refined risk characterization for wildlife resulted in the identification of no chemicals with a LOAEL-based HQ greater than 1.

After consideration of the results of the SLERA, background concentrations, uncertainty associated with plant and invertebrate toxicity values, and the nature of the waste historically disposed of at the site, the SMDP is the following:

There is adequate information to conclude that ecological risks are negligible and therefore there is no need for further action at the site on the basis of ecological risk.

7.3 SLERA RESULTS – SWMU 37

7.3.1 Preliminary Risk Characterization

The complete preliminary risk characterization tables are provided in Appendix F.3 and summarized below.

7.3.1.1 Terrestrial Plants

Direct contact HQs calculated for plants are presented in Table F.3-6 for detected chemicals. Of the detected chemicals for which screening values were available, the concentrations of aluminum, calcium, chromium, copper, lead, manganese, mercury, nickel, and vanadium resulted in HQ values greater than 1.

7.3.1.2 Soil Invertebrates and Microbial Communities

Direct contact HQs calculated for invertebrates are presented in Table F.3-8 for detected chemicals. Of the detected chemicals for which screening values were available, the concentrations of chromium, copper, iron, manganese, mercury, vanadium, and zinc resulted in HQ values that were greater than 1.

7.3.1.3 Terrestrial Wildlife

Quantitative risk characterization for terrestrial wildlife is limited to direct ingestion of biota and incidental ingestion of soil. The risk for detected bioaccumulative chemicals is summarized in Table F.3-24 for each terrestrial wildlife receptor and the chemicals with HQs greater than 1 are characterized as follows:

Receptor	NOAEL Only HQ>1	NOAEL and LOAEL HQ>1
Meadow Vole	cadmium, chromium, lead	arsenic, copper, selenium
Short-tailed Shrew	lead, zinc, dieldrin	arsenic, cadmium, chromium, copper, Aroclor 1254
Red Fox	nickel, selenium, dieldrin	arsenic, cadmium, chromium, copper, lead, zinc, Aroclor 1254
American Robin	nickel, selenium, dieldrin	cadmium, chromium, copper, lead, mercury, zinc, Aroclor 1254, 2,4-DNT
Red-tailed Hawk	chromium, lead, zinc	none

7.3.2 Refined Risk Characterization

The complete refined risk characterization tables are provided in Appendix F.3 and summarized below.

7.3.2.1 Terrestrial Plants

Direct contact HQs calculated for plants are presented in Table F.3-6 for detected chemicals. Of the detected chemicals for which screening values were available, the concentrations of aluminum, calcium, chromium, copper, lead, manganese, mercury, nickel, and vanadium resulted in HQ values greater than 1.

7.3.2.2 Soil Invertebrates and Microbial Communities

Direct contact HQs calculated for invertebrates are presented in Table F.3-8 for detected chemicals. Of the detected chemicals for which screening values were available, the concentrations of chromium, copper, iron, mercury, and vanadium resulted in HQ values that were greater than 1.

7.3.2.3 Terrestrial Wildlife

The refined risk characterization results are presented in Table F.3-24 and summarized below for each of the receptors with chemical HQs greater than 1:

Receptor	NOAEL Only HQ>1	NOAEL and LOAEL HQ>1
Meadow Vole	none	none
Short-tailed Shrew	arsenic (1.5), Aroclor 1254 (6.3)	none
Red Fox	none	none
American Robin	chromium (4.1), lead (4.7), zinc (2.2)	none
Red-tailed Hawk	none	none

*Note: (31/16) = NOAEL-based HQ/LOAEL-based HQ

7.3.3 Risk Management - Scientific Management Decision Point

Terrestrial plant COPECs with refined HQs greater than 1 included: aluminum, calcium, chromium, copper, lead, manganese, mercury, nickel, and vanadium. Although the refined aluminum HQ is greater than 1, the average pH in the soil is greater than 5.5 (see Appendix C.1). Therefore, since aluminum is biologically inactive in circumneutral to alkaline conditions (pH 5.5-8.0) such as those present at the site, aluminum is not considered a COPEC (USEPA 2003). Lead, manganese, and vanadium are consistently below background (see Appendix D.2, Table D.2-2a); therefore, these chemicals are not considered site-related. A discussion of the methodology of site versus background comparison is provided in Section 6.4.3. Even though the refined HQs for copper (2.1) and nickel (1.3) are greater than 1 and concentrations at the site are above background concentrations via means comparison, this risk presents low to negligible risk to plants at the site. The plant screening levels for calcium, chromium, and mercury are ORNL plant screening levels rather than ECO SSLs introducing uncertainty into the HQ calculations due to the uncertainty associated with these toxicity values. For example, the ORNL screening level is used for chromium, but during the development of ECO SSLs for chromium, it was determined that not enough data was available to derive an ECO SSL for plants; therefore, the data collected for the ORNL study was determined to be insufficient. In addition it is important to note that although metals concentrations in plants were above the screening levels, vegetation at the site is lush and diverse and indications of chemical vegetative stress were not observed as shown in site photographs (Appendix A).

Soil invertebrates and microbial processes COPECs with refined HQs greater than 1 included: chromium, copper, iron, mercury, and vanadium. Iron and vanadium are consistently below background; therefore, these chemicals are not considered site-related. Even though the refined HQ for copper (1.8) is greater than 1 and concentrations at the site are above background concentrations via means comparison, this risk presents low to negligible risk to invertebrates at the site. The invertebrate and microbial processes screening levels for chromium and mercury are ORNL earthworm screening levels rather than ECO SSLs introducing uncertainty into the HQ calculations due to the uncertainty associated with these toxicity values. For example, the ORNL screening level is used for chromium, but during the development of ECO SSLs for chromium, it was determined that not enough data was available to derive an ECO SSL for invertebrates; therefore, the data collected for the ORNL study was determined to be insufficient.

The refined risk characterization for wildlife resulted in the identification of no chemicals with a LOAEL-based HQ greater than 1.

After consideration of the results of the SLERA, background concentrations, uncertainty associated with plant and invertebrate toxicity values, and the nature of the waste historically disposed of at the site, the SMDP is the following:

There is adequate information to conclude that ecological risks are negligible and therefore there is no need for further action at the site on the basis of ecological risk.

7.4 SLERA RESULTS – SWMU 38/AOC Q

7.4.1 Preliminary Risk Characterization

The complete preliminary risk characterization tables are provided in Appendix F.4 and summarized below.

7.4.1.1 Terrestrial Plants

Direct contact HQs calculated for plants are presented in Table F.4-6 for detected chemicals. Of the detected chemicals for which screening values were available, the concentrations of aluminum, calcium, chromium, copper, manganese, selenium, and vanadium resulted in HQ values greater than 1.

7.4.1.2 Soil Invertebrates and Microbial Communities

Direct contact HQs calculated for invertebrates are presented in Table F.4-8 for detected chemicals. Of the detected chemicals for which screening values were available, the concentrations of chromium, copper, iron, manganese, mercury, and vanadium resulted in HQ values that were greater than 1.

7.4.1.3 Terrestrial Wildlife

Quantitative risk characterization for terrestrial wildlife is limited to direct ingestion of biota and incidental ingestion of soil. The risk for detected bioaccumulative chemicals is summarized in Table F.4-24 for each terrestrial wildlife receptor and the chemicals with HQs great than 1 are characterized as follows:

Receptor	NOAEL Only HQ>1	NOAEL and LOAEL HQ>1
Meadow Vole	cadmium, copper, lead	arsenic, selenium
Short-tailed Shrew	arsenic, cadmium, chromium, copper, lead, selenium, zinc	Aroclor 1254
Red Fox	lead	arsenic, cadmium, chromium, copper, selenium , zinc, Aroclor 1254
American Robin	selenium, Aroclor 1254, 2,4-DNT	cadmium, chromium, lead, mercury, zinc
Red-tailed Hawk	chromium, zinc	none

7.4.2 Refined Risk Characterization

The complete refined risk characterization tables are provided in Appendix F.4 and summarized below.

7.4.2.1 Terrestrial Plants

Direct contact HQs calculated for plants are presented in Table F.4-6 for detected chemicals. Of the detected chemicals for which screening values were available, the concentrations of aluminum, calcium, chromium, manganese, selenium, and vanadium resulted in HQ values greater than 1.

7.4.2.2 Soil Invertebrates and Microbial Communities

Direct contact HQs calculated for invertebrates are presented in Table F.4-8 for detected chemicals. Of the detected chemicals for which screening values were available, the concentrations of chromium, iron, manganese, mercury, and vanadium resulted in HQ values that were greater than 1.

7.4.2.3 Terrestrial Wildlife

The refined risk characterization results are presented in Table F.4-24 and summarized below for each of the receptors with chemical HQs greater than 1:

Receptor	NOAEL Only HQ>1	NOAEL and LOAEL HQ>1
Meadow Vole	none	none
Short-tailed Shrew	Aroclor 1254 (4.2)	none
Red Fox	none	none
American Robin	chromium (1.8), lead (1.2), zinc (2.0)	none
Red-tailed Hawk	none	none

*Note: (1.4) = NOAEL-based HQ

7.4.3 Risk Management - Scientific Management Decision Point

Terrestrial plant COPECs with refined HQs greater than 1 included: aluminum, calcium, chromium, manganese, selenium, and vanadium. Although the refined aluminum HQ is greater than 1, the average pH in the soil is greater than 5.5 (see Appendix C.1). Therefore, since aluminum is biologically inactive in circumneutral to alkaline conditions (pH 5.5-8.0) such as those present at the site, aluminum is not considered a COPEC (USEPA 2003). Chromium, manganese, and vanadium are consistently below background (see Appendix D.2, Table D.2-3a); therefore, these chemicals are not considered site-related. A discussion of the methodology of site versus background comparison is provided in Section 6.4.3. Even though the refined HQ for selenium (1.2) is slightly greater than 1 and concentrations at the site are above background concentrations via means comparison, this risk presents low to negligible risk to plants at the site.

Soil invertebrates and microbial processes COPECs with refined HQs greater than 1 included: chromium, iron, manganese, mercury, and vanadium. Chromium, iron, manganese, and vanadium are consistently below background; therefore, these chemicals are not considered site-related. Even though the refined HQ for mercury (1.6) is greater than 1 and concentrations at the site are above background concentrations via means comparison, this risk presents low to negligible risk to invertebrates at the site.

The refined risk characterization for wildlife resulted in the identification of no chemicals with a LOAEL-based HQ greater than 1.

After consideration of the results of the SLERA, background concentrations, and the nature of the waste historically disposed of at the site, the SMDP is the following:

There is adequate information to conclude that ecological risks are negligible and therefore there is no need for further action at the site on the basis of ecological risk.

7.5 EXPOSURE AND RISK UNCERTAINTY ANALYSIS

Based on this assessment, while factors such as lack of TSV and wildlife profile assumptions may create limited uncertainty, the overall result of the conservative nature of the process has produced a conservative assessment of potential ecological risks associated with the site.

Assumptions and other factors that tend to overestimate, underestimate, or have an unknown effect on the findings of the ecological risk screening are presented below with a discussion of their uncertainty.

7.5.1 Data Quality

Insufficient sampling density or the analyte list may not provide a representative estimate of exposure to COPECs. Misrepresentation of exposure results in uncertainty and may lead to an overestimation or underestimation of risk. Ten or more sampling locations at each of the sites under consideration reduce

this uncertainty. Elevated reporting limits for chemicals, such as PAHs at SWMU 35, could result in an underestimation of risk at the site due to potentially failing to identify a COPEC. Moreover, the extensive list of constituents analyzed reduces the likelihood of failing to identify a COPEC. Therefore, the uncertainty in the ecological risk screening results associated with data quality is likely minimal.

7.5.2 COPEC Bioavailability

Chemical analyses of exposure media measured the total levels of the COPECs rather than the more bioavailable toxic forms. The availability of the total concentrations alone assumes that the entire fraction is bioavailable and toxic. This is likely to be a very conservative assumption that varies from constituent to constituent. It was also assumed that no geochemical factors limited receptor exposure to, or the potential for toxic expression of COPECs. It is likely that COPECs may, to some degree, adsorb to fine-grained particles and/or complex with chemical complexing agents and organic ligands in the exposure media. Such actions may change the chemical speciation of the COPECs to a less toxic form, or reduce the concentrations of bioavailable chemicals and subsequent uptake by receptors. Therefore, risk is likely to be overestimated.

7.5.3 Wildlife Profile Assumptions

Dose rate models require a number of assumptions, which could result in either an overestimation or underestimation of risk to receptors. For example, body weights and ingestion rates are estimated from limited information. In addition, receptors are assumed to feed on specified food sources, although some such as the Red Fox may feed opportunistically on a greater variety of food types.

Area use factors (AFs) were estimated based on the size of the site relative to the home ranges of the receptors. However, the foraging of birds and mammals is not assessed simply by size, but rather a function of habitat suitability, habitat productivity, and species-specific foraging behaviors. Therefore, because habitat quality is not accounted for in estimating AF, the risk to terrestrial receptors in this assessment is likely to be overestimated.

The qualitative nature of the conclusion of lack of risk to the plant community based on the lack of indicator of chemical vegetative stress and lush vegetation present at the site creates uncertainty since it is not known that if the local plant community shows a response in terms of lower species diversity, reduced growth, or other more subtle responses that might be observable when compared to an non-impacted reference location.

7.5.4 Lack of Toxicological Data

The evaluation of ecological effects was limited in the direct contact and wildlife ingestion pathways due to limited toxicological data of the COPECs. The effects of many COPECs evaluated for the direct contact pathway to invertebrates and microbial communities were not quantified due to the lack of invertebrate derived TRVs. In addition, NOAEL and LOAEL TRVs were not available for receptors exposed to multiple COPECs. Therefore, due to the lack of toxicological data, the risk to potential receptors may be underestimated or unknown.

7.5.5 TRVs

NOAEL and LOAEL TRVs identified for wildlife receptors represent the most conservative application of toxicity test results identified from the literature. High uncertainty factors were used to provide TRVs representative of chronic exposure and sub-lethal effects. This approach is likely to overestimate the sensitivity of many ecological receptors and likely overestimates risk to potential receptors.

7.5.6 Hazard Quotients

Uncertainties in characterizing risks are primarily associated with the assumption that an HQ greater than 1 is an adequate indicator of the potential for ecological risks of individual chemicals. Given the use of conservative and realistic exposure and effects assumptions previously discussed, there is minimal

uncertainty that the potential for ecological risks of individual chemicals are not identified in the ecological risk screening of the sites. Conversely, there is a strong possibility for false positive identification of ecological risks for some individual chemicals. An HQ of less than one indicates that the contaminant alone is unlikely to cause adverse ecological effects. The potential for risk increases as the HQ increases above one. However, this result should be considered in the context of other characteristic of the exposure area. In addition, it should be noted that the calculation of chemical specific HQs does not account for multiple chemicals acting through the same exposure mechanism.

7.5.7 Exposure and Risk Uncertainty Conclusions

While factors such as lack of TSV and wildlife profile assumptions may create limited uncertainty, the very small size and negligible habitat quality of the site in combination with these limited uncertainties has produced a conservative assessment of potential ecological risks associated with SWMU 35, SWMU 37, and SWMU 38/AOC Q.

7.6 CONCLUSIONS AND RECOMMENDATIONS

Based on the results of the SLERAs and risk management considerations, no need for further action is required at SWMU 35, SWMU 37, and SWMU 38/AOC Q on the basis of ecological risk.

8.0 CONCLUSIONS AND RECOMMEDATIONS

An RFI has been completed for SWMUs 35, 37, 38, and AOC Q, calcium sulfate lagoons, located in the MMA of the RFAAP. The purpose of the RFI was to evaluate potential releases to soil and groundwater at the sites.

Soil sampling with the RFI study areas indicated that metals were the primary COPCs for the sites. Manganese, chloroform, and pesticides (SWMU 37 only) were identified as the primary COPCs for the sites in groundwater.

HHRAs were performed to evaluate the potential human health effects associated with releases to soil and groundwater at the sites. Receptors evaluated included: current/future maintenance worker, hypothetical future construction worker, hypothetical future commercial worker, hypothetical future adult resident, hypothetical future child resident, and hypothetical future lifetime resident. Total carcinogenic risk calculated for each receptor was below or within USEPA's target risk range for Superfund sites (1E-06 to 1E-04, USEPA 1989) for the sites. The mean concentrations for lead in surface soil and total soil for SWMU 35 (233.6 mg/kg - surface soil and 137.1 mg/kg - total soil), SWMU 37 (121 mg/kg - surface soil and 64.05 mg/kg - total soil), and SWMU 38/AOC Q (26.61 mg/kg - surface soil and 17.63 mg/kg - total soil) were below the residential lead screening level of 400 mg/kg; therefore, additional lead modeling was not conducted for the sites. Total non carcinogenic hazards after consideration of target organs, background, and site specific conditions, for all receptors were equal to or below the USEPA reference HI of 1E+00 with the exception of the construction worker at each site due to aluminum (SWMU 35, SWMU 37, SWMU 38/AOCQ) and manganese (SWMU 38/AOC Q) in soil. Additional comparison of site soil concentrations to background point estimates (UTLs), indicated that the sites' soil concentration for these metals were not significantly above background. The results of the human health risk assessments did not indicate a requirement for further action for the sites.

SLERAs were performed to evaluate potential ecological risk associated with soil at the sites. Receptors evaluated included soil invertebrates and microbes, plants, and terrestrial wildlife. The results of the screening level ecological risk assessment indicated there is adequate information to conclude that ecological risks were not significant at the sites, and therefore, there was no need for further action for soil at the sites on the basis of ecological risk.

Based on the results of the RFI, HHRAs, and SLERAs, no further action is recommended for the sites.

STANDARD OPERATING PROCEDURE 10.1
FIELD LOGBOOK

1.0 SCOPE AND APPLICATION

The purpose of this standard operating procedure (SOP) is to delineate protocols for recording daily site investigation activities.

Records should contain sufficient information so that anyone can reconstruct the sampling activity without relying on the collector's memory.

2.0 MATERIALS

- Field Logbook;
- Indelible ink pen; and
- Clear tape.

3.0 PROCEDURE

Information pertinent to site investigations will be recorded in a bound logbook. Each page/form will be consecutively numbered, dated, and signed. All entries will be made in indelible ink, and all corrections will consist of line out deletions that are initialed and dated. If only part of a page is used, the remainder of the page should have an "X" drawn across it. At a minimum, entries in the logbook will include but not be limited to the following:

- Project name (cover);
- Name and affiliation of personnel on site;
- Weather conditions;
- General description of the field activity;
- Sample location;
- Sample identification number;
- Time and date of sample collection;
- Specific sample attributes (e.g., sample collection depth flow conditions or matrix);
- Sampling methodology (grab or composite sample);
- Sample preservation, as applicable;
- Analytical request/methods;
- Associated quality assurance/quality control (QA/QC) samples;
- Field measurements/observations, as applicable; and
- Signature and date of personnel responsible for documentation.

4.0 MAINTENANCE

Not applicable.

5.0 PRECAUTIONS

None.

STANDARD OPERATING PROCEDURE 10.2
SURFACE WATER, GROUNDWATER, AND SOIL/SEDIMENT FIELD LOGBOOKS

1.0 SCOPE AND APPLICATION

The purpose of this standard operating procedure (SOP) is to delineate protocols for recording surface water, groundwater, and soil/sediment sampling information, as well as instrument calibration data in field logbooks.

2.0 MATERIAL

- Applicable field logbook (see attached forms); and
- Indelible ink pen.

3.0 PROCEDURE

All information pertinent to surface water, groundwater, or soil/sediment sampling will be recorded in the appropriate logbook. Each page/form of the logbook will be consecutively numbered. All entries will be made with an indelible ink pen. All corrections will consist of line out deletions that are initialed and dated.

3.1 SOIL/SEDIMENT

3.1.1 Field Parameters/Logbook (Form 10.2-a)

1. HIGH CONCENTRATION EXPECTED?: Answer "Yes" or "No.";
2. HIGH HAZARD?: Answer "Yes" or "No.";
3. INSTALLATION/SITE: Record the complete name of the installation or site;
4. AREA: Record the area designation of the sample site;
5. INST. NAME: Record the two-letter installation name for Radford Army Ammunition Plant – "RD";
6. SAMPLE MATRIX CODE: Record the appropriate sample matrix code. Common codes are "SD" for solid - sediment, "SI" for soil - gas, "SL for solid sludge, "SO" for surface other, "SS" for solid – soil, "SW" for surface wipe, "WD" for water – potable, "WG" for water – ground, "WS" water – surface, "WT" – water treated and "WW" water -waste;
7. SITE ID: Record a code up to 20 characters or numbers that is unique to the site;
8. ENV. FIELD SAMPLE IDENTIFIER: Record a code up to 20 characters specific for the sample;
9. DATE: Enter the date the sample was taken;
10. TIME: Enter the time (12-hour or 24-hour clock acceptable as long as internally consistent) the sample was taken;
11. AM PM: Circle "AM" or "PM" to designate morning or afternoon (12-hour clock);
12. SAMPLE PROG: Record "RFI" (RCRA Facility Investigation) or other appropriate sample program;
13. DEPTH (TOP): Record the total depth sampled;
14. DEPTH INTERVAL: Record the intervals at which the plug will be sampled;
15. UNITS: Record the units of depth (feet, meters);

16. SAMPLE MEASUREMENTS: Check the appropriate sampling method;
17. CHK: Check off each container released to a laboratory;
18. ANALYSIS: Record the type of analysis to be performed on each sample container;
19. SAMPLE CONTAINER: Record the sample container type and size;
20. NO.: Record the number of containers;
21. REMARKS: Record any remarks about the sample;
22. TOTAL NUMBER OF CONTAINERS FOR SAMPLE: Record the total number of containers;
23. SITE DESCRIPTION: Describe the location where the sample was collected;
24. SAMPLE FORM: Record the form of the sample (i.e., clay, loam, etc.) using The Unified Soil Classification System (USCS);
25. COLOR: Record the color of the sample as determined from standard Munsell Color Charts;
26. ODOR: Record the odor of the sample or "none";
27. PID: Record the measured PID values or other similar measurement instrument value;
28. UNUSUAL FEATURES: Record anything unusual about the site or sample;
29. WEATHER/TEMPERATURE: Record the weather and temperature; and
30. SAMPLER: Record your name.

3.1.2 Map File Form (refer to form 10.2-c)

1. SITE ID: Record the Site ID from the field parameter form;
2. POINTER: Record the field sample number for the sample being pointed to;
3. DESCRIPTION/MEASUREMENTS: Describe the location where the sample was taken, along with distances to landmarks;
4. SKETCH/DIMENSIONS: Diagram the surroundings and record the distances to landmarks;
5. MAP REFERENCE: Record which U.S.G.S. Quad Map references the site;
6. COORDINATE DEFINITION: Write the compass directions and the X- and Y-coordinates of the map run;
7. COORDINATE SYSTEM: Write "UTM" (Universal Transverse Mercator);
8. SOURCE: Record the 1-digit code representing the Map Reference;
9. ACCURACY: Give units (e.g., write "1-M" for 1 meter);
10. X-COORDINATE: Record the X-coordinate of the sample site location;
11. Y-COORDINATE: Record the Y-coordinate of the sample site location;
12. UNITS: Record the units used to measure the map sections;
13. ELEVATION REFERENCE: Record whether topography was determined from a map or a topographical survey;
14. ELEVATION SOURCE: Record the 1-digit code representing the elevation reference;
15. ACCURACY: Record the accuracy of the map or survey providing the topographical information;

16. ELEVATION: Record the elevation of the sampling site;
17. UNITS: Write the units in which the elevation is recorded; and
18. SAMPLER: Write your name.

3.2 SURFACE WATER

3.2.1 Field Parameter Logbook (Forms 10.2-b and 10.2-c)

1. CAL REF: Record the calibration reference for the pH meter;
2. pH: Record the pH of the sample;
3. TEMP: Record the temperature of the sample in degrees Celsius;
4. COND: Record the conductivity of the water;
5. Description of site and sample conditions (refer to 10.2-b);
6. Map File Form (refer to Section 3.1.2).

3.3 GROUNDWATER (FORMS 10.2- D)

3.3.1 Field Parameter Logbook (Form 10.2.b)

Refer to Section 3.2.1.

3.3.2 Map File and Purging Forms

1. WELL NO. OR ID: Record the abbreviation appropriate for where the sample was taken. Correct abbreviations can be found on pages 18-21 of the IRDMIS User's Guide for chemical data entry;
2. SAMPLE NO.: Record the reference number of the sample;
3. WELL/SITE DESCRIPTION: Describe the location where the sample was taken, along with distances to landmarks;
4. X-COORD AND Y-COORD: Record the survey coordinates for the sampling site;
5. ELEV: Record the elevation where the sample was taken;
6. UNITS: Record the units the elevation was recorded in;
7. DATE: Record the date in the form MM/DD/YY;
8. TIME: Record the time, including a designation of AM or PM;
9. AIR TEMP.: Record the air temperature, including a designation of C or F (Celsius or Fahrenheit);
10. WELL DEPTH: Record the depth of the well in feet and inches;
11. CASING HEIGHT: Record the height of the casing in feet and inches;
12. WATER DEPTH: Record the depth (underground) of the water in feet and inches;
13. WELL DIAMETER: Record the diameter of the well in inches;
14. WATER COLUMN HEIGHT: Record the height of the water column in feet and inches;
15. SANDPACK DIAM.: Record the diameter of the sandpack. Generally, this will be the same as the bore diameter;

16. EQUIVALENT VOLUME OF STANDING WATER: Use one of the following equations to determine one equivalent volume (EV);

    1 EV = volume in casing + volume in saturated sandpack. Or:

    $1\ EV = [\pi R_w^2 h_w + 0.30p(R_s^2 - R_w^2)h_s] * (0.0043)$

Where:

R_s = radius of sandpack in inches
R_w = radius of well casing in inches
h_s = height of sandpack in inches
h_w = water depth in inches

$0.0043 = gal/in^3$
and filter pack porosity is assumed as 30%, or

Volume in casing =
$(0.0043\ gal/in^3)(p)(12\ in/ft)(R_c^2)(W_h)$

Where:

R_c = radius of casing in inches, and
W_h = water column height in feet

Vol. in sandpack =
(0.0043 gal/in3)(p)(12 in/ft)(Rb2 - Rc2)(Wh)(0.30)

(if Wh is less than the length of the sandpack), or

Vol. in sandpack =
(0.0043 gal/in3)(p)(12 in/ft)(Rb2 - Rc2)(Sh)(0.30)

(if Wh is greater than the length of the sandpack).

where:

Rb = radius of the borehole, and
Sh = length of the sandpack.

Show this calculation in the comments section.

1. PUMP RATE: Record pump rate;
2. TOTAL PUMP TIME: Record total purge time and volume;
3. WELL WENT DRY? Write “YES” or “NO”;
4. PUMP TIME: Record pump time that made the well go dry;
5. VOLUME REMOVED: Record the volume of water (gal) removed before the well went dry;
6. RECOVERY TIME: Record the time required for the well to refill;

7. PURGE AGAIN?: Answer “YES” or “NO”;
8. TOTAL VOL. REMOVED: Record the total volume of water (in gallons) removed from the well;
9. CAL REF.: Record the calibration reference for the pH meter;
10. TIME: Record time started (INITIAL T(0)), 2 times DURING the sampling and the time sampling ended (FINAL);
11. pH: Record the pH at start of sampling (INITIAL), twice DURING the sampling, and at the end of sampling (FINAL);
12. TEMP: Record the water temperature (Celsius) at the start of sampling, twice DURING the sampling, and at the end of sampling (FINAL);
13. COND: Record the conductivity of the water at the start of sampling, twice DURING the sampling, and at the end of sampling (FINAL);
14. D.O.: Record the dissolved oxygen level in the water at the start of sampling, twice DURING the sampling, and at the end of sampling (FINAL);
15. TURBIDITY: Record the readings from the turbidity meter (nephelometer) and units at the start of sampling, twice DURING the sampling, and at the end of sampling (FINAL);
16. ORD: Record the oxidation/reduction (RedOx) potential of the water sample at the start of sampling, twice DURING the sampling, and at the end of sampling (FINAL);
17. HEAD SPACE: Record any positive readings from organic vapor meter reading taken in well headspace before sampling;
18. NAPL: Record the presence and thickness of any non-aqueous phase liquids (LNAPL and DNAPL)
19. COMMENTS: Record any pertinent information not already covered in the form; and
20. SIGNATURE: Sign the form.

3.4 FIELD CALIBRATION FORMS (REFER TO FORM 10.2-E)

1. Record time and date of calibration;
2. Record calibration standard reference number;
3. Record meter ID number;
4. Record initial instrument reading, recalibration reading (if necessary), and final calibration reading on appropriate line;
5. Record value of reference standard (as required);
6. COMMENTS: Record any pertinent information not already covered on form; and
7. SIGNATURE: Sign form.

STANDARD OPERATING PROCEDURE 10.3
BORING LOGS

1.0 INTRODUCTION

The purpose of this standard operating procedure (SOP) is to describe the methods to be followed for classifying soil and rock, as well as preparing borehole logs and other types of soil reports.

2.0 MATERIALS

The following equipment is required for borehole logging:

- HTRW ENG Form 5056-R and 5056A-R boring log forms;
- Daily inspection report forms;
- Chain-of-custody forms;
- Request for analysis forms;
- ASTM D 2488 classification flow chart;
- Soil and/or Rock color chart (i.e., Munsell®);
- Grain size and roundness chart;
- Graph paper;
- Engineer's scale;
- Previous reports and boring logs;
- Pocketknife or putty knife;
- Hand lens;
- Dilute hydrochloric acid (10% volume);
- Gloves;
- Personal protective clothing and equipment, as described in work plan addenda health and safety plan;
- Photoionization detector or other appropriate monitoring equipment per site-specific health and safety plan; and
- Decontamination supplies (SOP 80.1).

3.0 PROCEDURE

Each boring log should fully describe the subsurface environment and the procedures used to obtain this description.

Boring logs should be prepared in the field on USACE Engineer Form 5056-R and 5056-R. Logs should be recorded in the field directly on the boring log form and not transcribed from a field book.

A "site geologist" should conduct borehole logging and soil/rock identification and description or other professional trained in the identification and description of soil/rock.

3.1 BORING LOG INFORMATION

As appropriate, the following information should be recorded on the boring log during the course of drilling and sampling activities:

- Project information including name, location, and project number;
- Each boring and well should be uniquely numbered and located on a sketch map as part of the log;
- Type of exploration;
- Weather conditions including events that could affect subsurface conditions;
- Dates and times for the start and completion of borings, with notations by depth for crew shifts and individual days;
- Depths/heights in feet and in decimal fractions of feet;
- Descriptions of the drilling equipment including rod size, bit type, pump type, rig manufacturer and model, and drilling personnel;
- Drilling sequence and descriptions of casing and method of installation;
- Description and identification of soils in accordance with ASTM Standard D 2488;
- Descriptions of each intact soil sample for the parameters identified in Section 3.2;
- Descriptions and classification of each non-intact sample (e.g., wash samples, cuttings, auger flight samples) to the extent practicable;
- Description and identification of rock;
- Description of rock (core(s)) for the parameters identified in Section 3.7;
- Scaled graphic sketch of the rock core (included or attached to log) according to the requirements identified in Section 3.7;
- Lithologic boundaries, with notations for estimated boundaries;
- Depth of water first encountered in drilling, with the method of first determination (any distinct water level(s) below the first zone will also be noted);
- Interval by depth for each sample taken, classified, and/or retained, with length of sample recovery and sample type and size (diameter and length);
- Blow counts, hammer weight, and length of fall for driven samplers;
- Rate of rock coring and associated rock quality designation (RQD) for intervals cored;
- Drilling fluid pressures, with driller's comments;
- Total depth of drilling and sampling;
- Drilling fluid losses and gains should be recorded;
- Significant color changes in the drilling fluid returned;
- Soil gas or vapor readings with the interval sampled, with information on instrument used and calibration;

- Depth and description of any in-situ test performed; and
- Description of other field tests conducted on soil and rock samples.

3.2 SOIL PARAMETERS FOR LOGGING

In general, the following soil parameters should be included on the boring log when appropriate:

- Identification per ASTM D 2488 with group symbol;
- Secondary components with estimated percentages per ASTM D 2488;
- Color;
- Plasticity per ASTM D 2488;
- Density of non-cohesive soil or consistency of cohesive soil;
- Moisture condition per ASTM D 2488 (dry, moist, or wet);
- Presence of organic material;
- Cementation and HCL reaction testing per ASTM D 2488;
- Coarse-grained particle description per ASTM D 2488 including angularity, shapes, and color;
- Structure per ASTM D 2488 and orientation;
- Odor; and
- Depositional environment and formation, if known.

ASTM D 2488 categorizes soils into 13 basic groups with distinct geologic and engineering properties based on visual-manual identification procedures. The following steps are required to classify a soil sample:

1. Observe basic properties and characteristics of the soil. These include grain size grading and distribution, and influence of moisture on fine-grained soil.
2. Assign the soil an ASTM D 2488 classification and denote it by the standard group name and symbol.
3. Provide a written description to differentiate between soils in the same group if necessary.

Many soils have characteristics that are not clearly associated with a specific soil group. These soils might be near the borderline between groups, based on particle distribution or plasticity characteristics. In such a case, assigning dual group names and symbols (e.g., GW/GC or ML/CL) might be an appropriate method of describing the soil. The two general types of soils, for which classification is performed, coarse- and fine-grained soils, are discussed in the following sections.

3.3 COURSE-GRAINED SOIL IDENTIFICATION

For soils in the coarse-grained soils group, more than half of the material in the soil matrix will be retained by a No. 200 sieve (75-μm).

1. Coarse-grained soils are identified on the basis of the following:
    a) Grain size and distribution;
    b) Quantity of fine-grained material (i.e., silt and clay as a percentage); and
    c) Character of fine-grained material.

2. The following symbols are used for classification:

Basic Symbols			Modifying Symbols
G	=	gravel	W = well graded
S	=	sand	P = poorly graded
			M = with silty fines
			C = with clayey fines

3. The following basic facts apply to coarse-grained soil classification.

- The basic symbol G is used if the estimated percentage of gravel is greater than that for sand. In contrast, the symbol S is used when the estimated percentage of sand is greater than the percentage of gravel.
- Gravel ranges in size from 3-inch to 1/4-inch (No. 4 sieve) diameter. Sand ranges in size from the No. 4 sieve to No. 200 sieve. The Grain Size Scale used by Engineers (ASTM Standard D 422-63) is the appropriate method to further classify grain size as specified by ASTM D 2488.
- Modifying symbol W indicates good representation of all particle sizes.
- Modifying symbol P indicates that there is an excess or absence of particular sizes.
- The symbol W or P is used only when there are less than 15% fines in a sample.
- Modifying symbol M is used if fines have little or no plasticity (silty).
- Modifying symbol C is used if fines have low to high plasticity (clayey).

Figure 10.03a is a flowchart for identifying coarse-grained soils by ASTM D 2488.

3.4 FINED-GRAINED SOIL IDENTIFICATON

If one-half or more of the material will pass a No. 200 sieve (75 μm), the soil is identified as fine-grained.

1. Fine-grained soils are classified based on dry strength, dilatancy, toughness, and plasticity.
2. Classification of fine-grained soils uses the following symbols:

Basic Symbols			Modifying Symbols		
M	=	silt (non plastic)	L	=	low liquid limit (lean)
C	=	clay (plastic)	H	=	high liquid limit (fat)
O	=	organic			
Pt	=	peat			

3. The following basic facts apply to fine-grained soil classification:
    - The basic symbol M is used if the soil is mostly silt, while the symbol C applies if it consists mostly of clay.
4. Use of symbol O (group name OL/OH) indicates that organic matter is present in an amount sufficient to influence soil properties. The symbol Pt indicates soil that consists mostly of organic material.

- Modifying symbols (L and H) are based on the following hand tests conducted on a soil sample:
    — Dry strength (crushing resistance).
    — Dilatancy (reaction to shaking).

— Toughness (consistency near plastic limit).

- Soil designated ML has little or no plasticity and can be recognized by slight dry strength, quick dilatency, and slight toughness.
- CL indicates soil with slight to medium plasticity, which can be recognized by medium to high dry strength, very slow dilatancy, and medium toughness.

Criteria for describing dry strength per ASTM D 2488 are as follows:

Description	Criteria
None	Dry sample crumbles into powder with pressure of handling
Low	Dry specimen crumbles into powder with some finger pressure
Medium	Dry specimen breaks into pieces or crumbles with considerable finger pressure
High	Dry specimen cannot be broken with finger pressure but will break into pieces between thumb and a hard surface
Very high	Dry specimen cannot be broken between the thumb and a hard surface stiffness

Criteria for describing dilatancy per ASTM D 2488 are as follows:

None	No visible change in the sample
Slow	Water appears slow on the surface of the sample during shaking and does not disappear or disappears slowly upon squeezing
Rapid	Water appears quickly on the surface of the sample during shaking and disappears quickly upon squeezing

Criteria for describing toughness per ASTM D 2488 are as follows:

Description	Criteria
Low	Only slight pressure is required to roll the thread near the plastic limit and the thread and lump are weak and soft
Medium	Medium pressure is required to roll the thread to near the plastic limit and the thread and lump have medium stiffness
High	Considerable pressure is required to roll the thread to near the plastic limit and the thread and lump have very high stiffness

Figure 10.03b is a flowchart for identifying fine-grained soils by ASTM D 2488.

3.5 DENSITY AND CONSISTENCY

Relative density for coarse-grained soils and consistency for fine-grained soils can be estimated using standard penetration test blow count data (ASTM D 1586). The number of blows required for each 6 inches of penetration or fraction thereof is recorded. If the sampler is driven less than 18 inches, the number of blows per each complete 6-inch interval and per partial interval is recorded.

For partial increments, the depth of penetration should be recorded to the nearest 1 inch. If the sampler advances below the bottom of the boring under the weight of rods (static) and/or hammer, then this information should be recorded on the log.

The following are some "rule-of-thumb" guidelines for describing the relative density of coarse-grained soils:

Blow Count	Relative Density for Sand
0–4	Very loose
4–10	Loose
10–30	Medium dense
30–50	Dense
>50	Very Dense

The following are some "rule-of-thumb" guidelines for describing the consistency of fine-grained soils:

Blow Count	Consistency for Clays	Description
0–2	Very Soft	Sample sags or slumps under its own weight
2–4	Soft	Sample can be pinched in two between the thumb and forefinger
4–8	Medium Stiff	Sample can be easily imprinted with fingers
8–16	Stiff	Sample can be imprinted only with considerable pressure of fingers
16–32	Very Stiff	Sample can be imprinted very slightly with fingers
>32	Hard	Sample cannot be imprinted with fingers; can be pierced with pencil

3.6 OTHER DESCRIPTIVE INFORMATION

The approximate percentage of gravel, sand, and fines (use a percentage estimation chart) should be recorded per ASTM D 2488 as follows:

Modifiers	Descriptions
Trace	Less than 5%
Few	5%–10%
Little	15%–25%
Some	30%–45%
Mostly	50%–100%

Color/discoloration should be recorded and described using a soil color chart, such as the Munsell® Soil Color Charts. A narrative and numerical description should be given from the color chart, such as Brown 10 YR, 5/3 (Munsell®). Odor should be described if organic or unusual.

Plasticity should be described as follows:

Description	Criteria
Non-plastic	A 1/8-inch thread cannot be rolled at any water content
Low	Thread can barely be rolled and lump cannot be formed when drier than plastic limit.
Medium	Thread is easy to roll; plastic limit can be reached with little effort and lump crumbles when drier than plastic limit.
High	Considerable time is required to reach the plastic limit and lump can be formed without crumbling when drier than plastic limit

Moisture condition should be recorded as dry (absence of moisture), moist (damp but no visible water) or wet (visible free water).

Cementation should be recorded (carbonates or silicates) along with the results of HCL reaction testing. The reaction with HCL should be described as none (no visible reaction), weak (some reaction with slowly forming bubbles) or strong (violent reaction with bubbles forming immediately).

Particle description information for coarse-grained soil should be recorded where appropriate per ASTM D 2488 including maximum particle size, angularity (angular, subangular, subrounded, or rounded), shape (flat, elongated or flat and elongated), and color.

Structure (along with orientation) should be reported using the following ASTM D 2488 descriptions:

Description	Criteria
Stratified	Alternating layers of varying material or color with layers greater than 6 millimeters thick
Laminated	Alternating layers of varying material or color with layers less than 6 millimeters thick
Fissured	Breaks along definite planes of fracture with little resistance
Slickensided	Fracture planes that appear polished or glossy, can be striated
Blocky	Inclusion of small pockets of different soils
Homogeneous	Same color and appearance throughout

3.7 ROCK CORE PARAMETERS FOR LOGGING

In general, the following parameters should be included on the boring log when rock coring is conducted:

- Rock type;
- Formation;
- Modifier denoting variety;
- Bedding/banding characteristics;
- Color;
- Hardness;
- Degree of cementation;
- Texture;
- Structure and orientation;
- Degree of weathering;
- Solution or void conditions;
- Primary and secondary permeability including estimates and rationale; and
- Lost core interval and reason for loss.

A scaled graphic sketch of the core should provided on or attached to the log, denoting by depth, location, orientation, and nature (natural, coring-induced, or for fitting into core box) of all core breaks. Where fractures are too numerous to be shown individually, their location may be drawn as a zone.

The RQD values for each core interval (run) should be calculated and included on the boring log. The method of calculating the RQD is as follows per ASTM D 6032:

RQD = [Σ length of intact core pieces > 100 mm (4-inches)] x 100%/total core length.

3.8 PROCEDURES FOR ROCK CLASSIFICATION

For rock classification record mineralogy, texture, and structural features (e.g., biotite and quartz fine grains, foliated parallel to relict bedding oriented 15 to 20 degrees to core axis, joints coated with iron oxide). Describe the physical characteristics of the rock that are important for engineering considerations such as fracturing (including minimum, maximum, and most common and degree of spacing), hardness, and weathering.

1. The following is to be used as a guide for assessing fracturing:

AEG Fracturing	Spacing
Crushed	up to 0.1 foot
Intense	0.1–0.5 foot
Moderate	0.5 foot–10 feet
Slight	1.0 foot–3.0 feet
Massive	>3.0 feet

2. Record hardness using the following guidelines:

Hardness	Criteria
Soft	Reserved for plastic material
Friable	Easily crumbled by finger pressure
Low	Deeply gouged or carved with pocketknife
Moderate	Readily scratched with knife; scratch leaves heavy trace of dust
Hard	Difficult to scratch with knife; scratch produces little powder and is often faintly visible
Very Hard	Cannot be scratched with knife

3. Describe weathering using the following guidelines:

Weathering	Decomposition	Discoloration	Fracture Condition
Deep	Moderate to complete alteration of minerals feldspars altered to clay, etc.	Deep and thorough	All fractures extensively coated with oxides, carbonates, or clay
Moderate	Slight alteration of minerals, cleavage surface lusterless and stained	Moderate or localized and intense	Thin coatings or stains
Weak	No megascopic alteration of minerals	Slight and intermittent and localized	Few strains on fracture surfaces
Fresh	Unaltered, cleavage, surface glistening		

3.9 PROCEDURE FOR LOGGING REFUSE

The following procedure applies to the logging of subsurface samples composed of various materials in addition to soil as may be collected from a landfill or other waste disposal site.

1. Observe refuse as it is brought up by the hollow stem auger, bucket auger, or backhoe.

2. If necessary, place the refuse in a plastic bag to examine the sample.

3. Record observations according to the following criteria:

   - Composition (by relative volume), e.g., paper, wood, plastic, cloth, cement, or construction debris. Use such terms as "mostly" or "at least half." Do not use percentages;
   - Moisture condition: dry, moist, or wet;
   - State of decomposition: highly decomposed, moderately decomposed, slightly decomposed, etc.;
   - Color: obvious mottling and/or degree of mottling;
   - Texture: spongy, plastic (cohesive), friable;
   - Odor;
   - Combustible gas readings (measure down hole and at surface); and
   - Miscellaneous: dates of periodicals and newspapers, ability to read printed materials, degree of drilling effort (easy, difficult, and very difficult).

3.10 SUBMITTAL REQUIREMENTS

Each original boring log should be submitted to the Contracting Officer Representative (CRO) after completion of the boring. When a monitoring well will be installed in a boring, the boring log and well installation diagram should be submitted together.

4.0 MAINTENANCE

Not applicable.

5.0 PRECAUTIONS

Not applicable.

STANDARD OPERATING PROCEDURE 10.4
CHAIN-OF-CUSTODY FORM

1.0 SCOPE AND APPLICATION

The purpose of this standard operating procedure (SOP) is to delineate protocols for use of the chain-of-custody form. An example is provided as part of this SOP. Other formats with similar levels of detail are acceptable.

2.0 MATERIALS

- Chain-of-custody form; and
- Indelible ink pen.

3.0 PROCEDURE

1. Record the project name and number.
2. Record the project contact's name and phone number.
3. Print sampler's names in "Samplers" block.
4. Enter the Field Sample No.
5. Record the sampling dates for all samples.
6. List the sampling times (military format) for all samples.
7. Indicate, "grab" or "composite" sample with an "X."
8. Record matrix (e.g., aqueous, soil).
9. List the analyses/container volume across top.
10. Enter the total number of containers per Field Sample No. in the "Subtotal" column.
11. Enter total number of containers submitted per analysis requested.
12. State the carrier service and airbill number, analytical laboratory, and custody seal numbers.
13. List any comments or special requests in the "Remarks" section.
14. Sign, date, and time the "Relinquished By" section when the cooler is relinquished to the next party.
15. Upon completion of the form, retain the shipper copy and place the forms and the other copies in a zip seal bag to protect from moisture. Affix the zip seal bag to the inside lid of the sample cooler to be sent to the designated laboratory.

4.0 MAINTENANCE

Not applicable.

5.0 PRECAUTIONS

None.

STANDARD OPERATING PROCEDURE 20.1
MONITORING WELL INSTALLATION

1.0 SCOPE AND APPLICATION

The installation of monitoring wells is contingent upon the existing conditions at the project site. The purpose of this standard operating procedure (SOP) is to delineate the quality control measures required to ensure the accurate installation of monitoring wells. For a particular site investigation, the associated work plan addenda should be consulted for specific installation instructions. The term "monitoring wells", as used herein is defined to denote any environmental sampling well.

2.0 MATERIALS

2.1 DRILLING EQUIPMENT

- Appropriately sized drill rig adequately equipped with augers, bits, drill stem, etc;
- Steam cleaner and approved source water for decontamination of drilling equipment, etc.;
- Source of approved water;
- Photoionization detector or other appropriate monitoring instrument per the site-specific Health and Safety plan;
- Water level indicator (electrical);
- Weighted steel tape measure;
- Steel drums and other appropriate containers for investigation-derived materials (drill cuttings, contaminated PPE, decontamination solutions, etc.);
- Absorbent pads and/or logs;
- Personal protective equipment and clothing (PPE) per site-specific health and safety plan; and
- Decontamination supplies, pad with heavy plastic sheeting (SOP 80.1).

2.2 WELL INSTALLATION MATERIALS

Technical information on all installed materials (screens, riser pipe, filter pack, bentonite, cement, etc.) and representative samples of the proposed filter pack will be supplied to the Contracting Officer's Representative (COR) before initiating well installation.

Well screen slot size and filter pack gradation will be determined based on existing site geology before initiating site-specific investigations.

- Well screen :

  Polyvinyl Chloride (PVC): JOHNSON (or equivalent); PVC commercially slotted continuous slot, wire wrapped screen; 4-in. diameter.; SCH 40; SCH 80; flush-threaded (leak-proof) joints; PVC should conform to National Sanitation Foundation (NSF) Standard 14 for potable water usage or ASTM Standard Specification F 480 and bear the appropriate rating logo. PVC should be free of ink markings, cleaned, and prepackaged by manufacturer;

Stainless Steel: JOHNSON (or equivalent); stainless steel Vee-Wire continuous slot, wire wrapped screen; 304 stainless steel (unless the sum concentration of Cl^-, F^-, and Br^- is <1000 ppm, case type 316 should be used); ASTM F 480 flush threads; cleaned, wrapped, and heat-sealed by manufacturer;

- Riser pipe:
  - PVC: JOHNSON (or equivalent); STD. PVC; 4-in. diameter.; SCH 40; SCH 80; flush-threaded (leak-proof) joints; PVC should conform to NSF Standard 14 or F 480; free of ink markings; cleaned and prepackaged by manufacturer;
  - Stainless Steel: JOHNSON (or equivalent); SCH 5; 304 stainless steel; ASTM type A312 material; 4-in. diameter.; cleaned, wrapped and heat-sealed by manufacturer;
- Plugs/Caps: JOHNSON (or equivalent); standard PVC or stainless steel;
- Filter pack: MORIE, clean sorted gravel (or equivalent);
- Bentonite seal: BAROID, bentonite pellets (3/8-in. diameter.);
- Cement: Type II Portland Cement; if sulfate concentrations are higher than 1500 ppm, Type IV Portland Cement will be used;
- Bentonite powder: BAROID, Aquagel Gold Seal;
- Steel Protective Casing: BRAINARD-KILMAN (or equivalent) zinc-plated steel, lockable, painted;
- Containers for purged water, as required;
- Submersible pump or bailer of appropriate capacity, and surge block sized to fit well;
- Hach DREL 2000 portable laboratory (or equivalent);
- Multiprobe Electronic Water Quality Recorder (Hydrolab);
- Electric well sounder and measuring tape;
- Portland Type II cement (see footnote); and
- Steel Posts (pickets), painted (see footnote).

2.3 DOCUMENTATION

- Copy of work plans and health and safety plan;
- Copy of USACE EM 110-1-4000 Monitoring Well Requirements;
- Copies of permits (area entry, hot work, well, and utility clearance);
- Boring log forms;
- Well completion diagram form; and
- Field logbook.

2.4 GEOLOGIST'S PERSONAL EQUIPMENT

- Boring log materials per SOP 10.3; and
- Personal protective equipment and clothing (PPE) as required by the site-specific health and safety plan.

3.0 PROCEDURE

3.1 MATERIALS APPROVAL

3.1.1 Source Water

Water sources for drilling, grouting, sealing, filter pack placement, well installation, and equipment decontamination must be approved by the COR before arrival of the drilling equipment. Information required for the water source includes:

- Water source;
- Manufacturer/owner and their address and telephone number;
- Type of treatment and filtration prior to tap;
- Time of access;
- Cost per gallon (if applicable); and
- Dates and results associated with all available chemical analyses over the past 2 years, and the name and address of the analytical laboratory (if applicable).

3.1.2 Bentonite

Pure sodium bentonite with no additives (bentonite) will be the only drilling fluid additive allowed, and its use must be approved by the COR before the arrival of the drilling equipment. The information required for evaluation includes brand name, manufacturer, manufacturer's address and telephone number, product description, and intended use for the product, and potential effects on chemical analysis of water samples.

3.1.3 Granular Filter Pack

Granular filter pack material must be approved by the COR before drilling. A one-pint representative sample must be supplied to the COR. Information required includes lithology, grain size distribution, brand name, source, processing method, and size of intended screen.

3.1.4 Cement

Portland Type II cement will be used for grout (or Type IV, as noted in Section 2.2).

3.2 DRILLING

The objective of the selected drilling technique used at given site is to ensure that the drilling method provides representative data while minimizing subsurface contamination, cross contamination, and drilling costs.

Drilling methods that are appropriate for boring or monitoring well installation will depend on the subsurface geology most likely to be encountered in the boring. The geology for each site should be determined by reviewing previous investigation data (boring data, geophysics, etc.) from the site or nearby areas. Specific drilling methods that will be used to support site activities will be incorporated into work plan addenda.

Section 5.2.2 of the Master Work Plan discusses the different drilling methods that may be appropriate for installation of monitoring wells at the Radford Army Ammunition Plant (RFAAP) based on the different types of conditions encountered. The different drilling methods discussed in this section of the Master Work Plan including:

- Hollow Stem Auger (for soil);
- Air Rotary (soil and rock);

- Water Rotary and wire-line casing advancement (soil and rock);
- Drill-Through-Casing Driver (soil and rock); and
- Sonic (soil and rock).

3.2.1 Responsibilities of the Site Geologist

A Site Geologist will be present during all well drilling and installation activities and will fully characterize all tasks performed in support of these activities in the monitoring well logbook. The Site Geologist will be responsible for the logging samples, monitoring drilling operations, recording water losses/gains and groundwater data, preparing the boring logs and well diagrams, and recording the well installation procedures for one operating rig. The Site Geologist will have sufficient equipment in operable condition on-site to perform efficiently his/her duties.

3.2.2 Additives

No lubricants will be used on down hole drilling equipment. Additives containing either lead or copper will not be allowed. In addition, polychlorinated biphenyls will not be permitted in hydraulic fluids or other fluids used in the drilling rig, pumps, or other field equipment and vehicles.

Surface runoff or other fluids will not be allowed to enter any boring or well during or after drilling/construction.

Antifreeze used to keep equipment from freezing will not contain rust inhibitors and sealants. Antifreeze is prohibited in any areas in contact with drilling fluid. Absorbent pillows will be placed to catch any obvious leaks from the drill rig.

3.2.3 Boring Logs and Field Notes

Borings for monitoring wells will be logged by a geologist as described in SOP 10.3. Logs will be recorded on USACE HTRW ENG Form 5056-R and 5056A-R boring log forms.

Daily investigation activities at the site related to drilling should be recorded in field logbooks as described in SOPs 10.1 and 10.2.

3.3 WELL CONSTRUCTION AND INSTALLATION

Specifications for monitoring well construction and installation for a given site being investigated are to be included in work plan addenda. In case the previously defined criteria have not been met before the depth range for a given hole is reached, the geologist will stop the drilling and confer with the supervisor. The current boring conditions (depth, nature of the stratigraphic unit, and water-table depth) will be compared to those of other wells nearby to decide whether to continue drilling or to terminate and complete the well.

3.3.1 Overburden Wells

Overburden wells at the RFAAP are typically designed as a 4-inch diameter, single cased well (see Figure 20-1a) installed into a surficial aquifer, which is present above bedrock. For this type of well, the well boring would be terminated before penetrating any underlying confining unit and/or bedrock.

Section 5.2.2 of the Master Work Plan discusses the different drilling methods that may be appropriate for installation of overburden wells.

If dense, non-aqueous liquid (DNAPL) is encountered during drilling, the well boring will be terminated and completed at the base of the overburden aquifer being monitored.

3.3.2 Bedrock Wells

Multi-cased wells or wells with an outer casing installed into competent bedrock should be specified for wells that are designed to monitor groundwater within bedrock (see Figure 20-1c). The installation of a multi-cased well or outer casing will isolate the zone(s) monitored from overburden and will minimize the potential for cross-contamination during and after drilling.

The general procedure to be followed for installation of a multi-cased well is as follows. This procedure assumes the installation of a 4-inch diameter monitoring well. Specific procedures, drilling techniques and design of monitoring wells will be presented in work plan addenda for site-specific investigations.

1. If soil sampling is required within overburden, use appropriate drilling techniques to advance the boring and collect the soil samples.

2. A minimum 10-inch drill bit should be advanced from the surface into competent bedrock a distance not less than 2 feet. A drilling technique appropriate for penetrating overburden and bedrock should be used such as air rotary.

3. After the borehole has been advanced to the target depth within competent bedrock, a 6-inch diameter steel or Schedule 80 PVC outer casing should be lowered to the bottom of the boring.

4. Once the outer casing has been lowered to the bottom of the boring, the casing should be grouted in-place using a decontaminated tremie pipe equipped with a side discharge. The annulus between the outer casing and borehole wall will be injected with grout until undiluted grout reaches the surface.

5. The grouting mixture, specification, and placement should be consistent with the requirements identified in Section 3.3.8.

6. The grout should be allowed to cure a minimum of 24 hours before further drilling.

7. After adequate curing time for outer casing, drilling with a 5-5/8-inch bit until the desired total depth is reached should complete the well boring.

8. Once the well boring is completed, an appropriate bedrock well will be constructed based on site-specific conditions. The types of wells that may be installed may include a constructed well with screen, casing, filter pack, seal, and grout; an open-bedrock well; or a lined open bedrock well (see Section 3.3.3).

3.3.3 Well Screen Usage

Well screen usage for a given site should be specified in work plan addenda based on expected site conditions.

In general, wells installed within overburden will be installed with a screen as per Figure 20.01-a or 20.01-b. Bedrock wells may be installed with or without a screen depending on site specific conditions such as the depth of water bearing zones, stability of bedrock, occurrence of karst zones, and construction of existing wells at the site being investigated.

In general, bedrock wells installed within karst zones will be completed as open-hole construction (see Figure 20.01c). If evidence of potential or severe borehole collapse (unstable bedrock) is indicated during drilling, casing and screen will be installed in the borehole as a removable lining. If desired, multiple flow zones may be monitored in an open bedrock well by installing a multiport well, which has monitoring/sampling intervals sealed off from the rest of the boring and from each other by packers.

3.3.4 Beginning Well Installation

Schedule

Monitoring well installation should begin within 12 hours of boring completion for holes that are uncased or partially cased with temporary drill casing. In the case where a partially cased hole into bedrock is to be partially developed prior to well insertion, the well installation should begin within 12 hours of this initial development. For holes that are fully cased, installation should begin within 48 hours. Once begun, well installation should not be interrupted.

Placement of Materials

Temporary casing and hollow stem augers may be removed from the boring prior to well installation if the potential for cross contamination is low and if the borehole will remain stable during the time required for installation.

Where borehole conditions are unstable, some or all of the well materials may need to be installed prior to removal of the temporary casing or hollow stem augers. The casing or hollow stem augers should have an inside diameter sufficient to allow the installation of the screen and casing plus annular space for a pipe through which to place filter pack and grout.

Any materials blocking the bottom of the drill casing or hollow stem auger should be dislodged and removed from the casing prior to well insertion.

3.3.5 Screens, Casing, and Fittings

Borehole Specifications

The borehole for each well should be of sufficient diameter to provide for at least 2 inches of annular space between the borehole wall and all sides of the casing.

Well Screens

Material specifications for well screens, casings, and fittings are discussed in Section 2.2.

Screen bottoms should be securely fitted with a threaded cap or plug of the same composition as the screen. The cap/plug should be within 0.5 feet of the open portion of the screen. A sediment trap/sump will not be used.

Screen slot size will be appropriately sized to retain 90%–100% of the filter pack material, the size of which will be determined by sieve analysis of formation material.

Well screen lengths should be specified in work plan addenda and will be based on various site-specific factors such as environmental setting, subsurface conditions, analytes of concern, regulatory considerations, etc.

Assembly and Placement of Well Screen and Casing

Personnel should take precautions to assure that grease, oil, or other contaminants do not contact any portion of the well screen and casing assembly. Clean latex or nitrile gloves should be worn when handling the screen and casing assembly. Flush, threaded joints usually can be tightened by hand. If necessary, steam cleaned wrenches may be used to tighten joints.

In general, each section of the well assembly is lowered into the borehole, one section at a time, screwing each section securely into the section below it. No grease, lubricant, polytetrafluoroethylene (PTFE) tape, or glue may be used in joining the sections of screen and casing.

The assembly should be lowered to its predetermined level and held in position for placement of the filter pack. It is essential that the assembly be installed straight (with centralizers as appropriate) to allow for

appropriate sampling. Buoyant forces associated with fluids in the borehole may require that the assembly be installed with the aid of hydraulic rams of the drill rig. When the well assembly is placed to predetermined level, a temporary cap should be place on the well to prevent foreign material from entering the well.

The bottoms of well screens should be placed no more than 3 feet above the bottom of the drilled borehole. If significant overdrilling is required, a pilot boring should be used. Sufficient filter pack should be placed at the bottom of the borehole

The well casing should be pre-cut (square) to extend 2 to 2.5 feet above the ground surface. Before placement of the last piece of well casing, a notch or other permanent reference point will be cut, filed, or scribed into the top edge of the casing.

The tops of all well casing will be capped with covers composed of materials compatible with the products used in the well installation. Caps will be loose fitting, constructed to preclude binding to the well casing caused by tightness of fit, unclean surfaces, or weather conditions. In either case, it should be secure enough to preclude the introduction of foreign material into the well, yet allow pressure equalization between the well and the atmosphere.

The top of each well casing should be level so that the maximum difference in elevation between the highest and lowest points of the casing is less than or equal to 0.02 ft.

3.3.6 Filter Pack

The volume of filter pack that is required to fill the annular between the well screen/casing and borehole should be computed, measured, and recorded.

Granular filter packs will be chemically and texturally clean, inert, and siliceous. The gradation of filter packs will be selected based on the screen size used and will be specified in the work plan addenda for the site being investigated.

Primary Filter Pack

Filter pack material should be placed in the borehole using a decontaminated tremie pipe. An appropriate amount of primary filter pack should be placed in the borehole prior to final positioning of the well screen to provide an appropriate barrier between the bottom of the borehole and the bottom of the screen. Once the initial filter pack has been placed and the well assembly is appropriately positioned and centered in the borehole, the remaining primary filter pack should be placed in increments (and tamped) as the tremie pipe is gradually raised.

As the primary filter pack is placed, approved source water may need to be added to help move the filter pack. A weighted tape should be used to measure the top of the filter pack as it is being placed. If bridging of the filter pack occurs, then this bridging should be broken mechanically prior to adding additional filter pack.

When temporary casing or hollow stem augers are used, the casing or augers should be removed in increments such that lifting of the well assembly is minimal. After removal of each increment, it should be confirmed by direct measurement that the primary filter pack has not been displaced during the removal.

The primary filter pack should extend from the bottom of the borehole to 3 to 5 ft above the top of the screen.

Secondary Filter Pack

The primary filter pack may be capped with 1 to 2 feet of feet of secondary filter pack to prevent the intrusion of the bentonite seal into the primary filter pack. The need for this filter pack (and specifications) should be addressed in work plan addenda for the site being investigated. Such factors as the gradation of the primary filter pack, the potential for grout extrusion, and site hydrogeology should be considered when evaluating the need for this filter pack.

3.3.7 Bentonite Seal

A bentonite seal, consisting of hydrated 3/8-inch diameter. bentonite pellets, will be installed immediately above the filter pack. The seal may be installed with a tremie pipe, which is lowered to the top of the filter pack and slowly raised as the pellets fill the annular space. In deep wells, the pellets may bridge and block the tremie pipe; in this case, pellets may be placed by free fall into the borehole. A weighted tape should be used to measure the top of seal as it is installed.

When cement grout is to be used above the bentonite seal, a minimum of 3 to 4 hours should be allowed for hydration of the pellets.

When installing a seal above the water table, water should be added to the bentonite for proper hydration. In this case, the seal should be placed in lifts of 0.5 to 1 foot with each lift hydrated for a period of 30 minutes.
If the bentonite seal is to be installed far below the water table, a bentonite slurry seal will be installed. Cement-bentonite grout will not be used below the water table. The slurry will be mechanically blended aboveground to ensure a lump-free mixture. The slurry will consist of bentonite powder and approved water mixed to a minimum of 20 percent solids by weight of pumpable slurry with a density of 9.4 pounds per gallon or greater. The slurry will be pumped into place through a tremie pipe and measured as installed.
Bentonite seals should be 3 to 5 ft thick as measured immediately after placement. The final depth to the top of the bentonite seal will be measured and recorded before grouting.

3.3.8 Grout

Cement grout used in construction will be composed of the following:

- Type II Portland Cement (or Type IV as noted in Section 2.2);
- Bentonite (2 to 5% dry bentonite per 94-lb sack of dry cement); and
- A maximum of 6 to 7-gallons of approved water per 94-lb sack of cement

Neither additives nor borehole cuttings will be mixed with the grout. Bentonite will be added after the required amount of cement is mixed with the water.

All grout material will be combined in an aboveground container and mechanically blended to produce a thick, lump-free mixture. The mixed grout will be recirculated through the grout pump before placement.
Grout placement should be performed as follows:

1. Grout should be placed from a rigid tremie pipe located just over the top of the bentonite seal. The tremie pipe should be decontaminated prior to use.
2. The tremie pipe should be kept full of grout from start to finish with the discharge end of the pipe completely submerged as it is slowly and continuously lifted.
3. The annulus between the drill casing and well casing should be filled with sufficient grout to allow for the planned drill casing removal. Grout should not penetrate the well screen or filter pack.
    - For incremental removal of drill casing, grout should be pumped to maintain at least 10 ft of grout in the drill casing remaining in the borehole after removing the selected length of casing. After each section of casing is removed, the tremie pipe may be reinserted to the base of the casing not yet removed.
    - In the case where drill casing will be removed all at once, grout should be pumped from the tremie pipe until undiluted grout flows from the annulus at the ground surface.

4. If the un-grouted portion of a borehole is less than 15 feet and without fluids after drill casing removal, then the un-grouted portion may be filled by pouring grout from the surface.
5. If drill casing was not used for well installation, grouting should proceed to the surface in one continuous operation.
6. For grout placement in a dry and open hole less than 15 ft deep, grout may be manually mixed and poured in from the surface providing that integrity of the bentonite seal is maintained.
7. Protective casing should be installed immediately after completion of grouting.
8. Grout settlement should be checked within 24 hours of the initial grout placement. Additional grout should be added grout should be added to fill any observed depressions.

The following will be noted in the boring logs: (1) exact amounts of cement, bentonite, and water used in mixing grout and (2) actual volume of grout placed in the hole.

3.3.9 Well Protection

The major elements of well protection will include:

- A protective casing;
- Protective concrete pad around the well; and
- Protective steel posts set around the well outside of the concrete pad.

Well Protective Casing

Well protective casings will be installed around all monitoring wells immediately after grouting. The protective casing should consist of a minimum 5-ft long, steel pipe (protective casing) installed over the well casing and into the grout. The protective casing should be installed to a depth of approximately 2.5-feet below ground surface (extending approximately 2.5 feet above ground surface). The internal well casing (riser) and protective casing will not be separated by more than 0.2 feet of height.

An internal mortar collar will be placed within the protective steel casing and outside the well casing to a height of 0.5 above ground surface.

After placement and curing of the mortar collar, an internal drainage hole will be drilled through the protective casing, which is centered no more than 1/8 inch above the grout filled annulus between the well riser and the protective casing.

Any annulus formed between the outside of the protective casing and the borehole will be filled to ground surface with cement.

Concrete Pad

After the grout has thoroughly set and the well protective casing has been installed, a protective concrete pad will be installed around the well. This pad will be at least 4 inches thick and 4 feet square and sloped away from the well to provide for adequate drainage.

Protective Posts

Additional protection will be provided at each well location by the installation of four steel posts outside of each corner of the concrete pad. The installation of protective posts should occur before the well is sampled.

The posts should have a minimum diameter of 3 inches, be placed 2 to 3 feet below ground surface, and extend at least 3 feet above ground surface. Posts should be painted orange using a brush.

Posts should be set in post holes, which are backfilled with concrete. For additional protection, the posts can be filled with concrete.

3.3.10 Well Construction Diagram and Field Notes

The construction of each well will be depicted as built in a well construction diagram (see Figure 20.1a). The diagram will be attached to the boring log and the following will be graphically denoted:

- Bottom of boring;
- Screen location, length, and size;
- Coupling locations;
- Granular filter pack;
- Seal;
- Grout;
- Cave-in;
- Centralizers;
- Height of riser;
- Protective casing detail;
- Water level 24 hours after completion with date and time of measurement;
- Quantity and composition of materials used; and
- Material between bottom of boring and bottom of screen.

Daily activities at the site related to monitoring well installation should be recorded in the field logbooks as described in SOPs 10.1 and 10.2.

3.4 GENERAL SEQUENCE OF MONITORING WELL COMPLETION

The following is a general sequence of monitoring well completion with reference to the specific details included in Section 3.3.

1. Completion of borehole;
2. Assembly and placement of well assembly as described in Section 3.3.5;
3. Placement of the appropriate filter pack(s) as discussed in Section 3.3.6;
4. Installation of an appropriate bentonite seal as discussed in Section 3.3.7;
5. Grouting the remaining annular space of the borehole as discussed in Section 3.3.8;
6. Set the protective casing for the well as discussed in Section 3.3.9;
7. Complete the protective concrete pad as discussed in Section 3.3.9; and
8. Install the protective posts as discussed in Section 3.3.9.

3.5 INVESTIGATION-DERIVED MATERIAL

Investigation-derived material will be managed in accordance with procedures defined in the work plan addenda for the site being investigated and SOP 70.1.

4.0 MAINTENANCE

Not applicable.

5.0 PRECAUTIONS

Refer to the site-specific health and safety plan.

STANDARD OPERATING PROCEDURE 20.2
MONITORING WELL DEVELOPMENT

1.0 SCOPE AND APPLICATION

Well development is the process by which drilling fluids, solids, and other mobile particulates within the vicinity of the newly installed monitoring well are removed, while ensuring proper hydraulic connection to the aquifer. Development stabilizes the formation and filter pack sands around the well screen to ensure aquifer water moves freely to the well.

Well development will be initiated not less than 48 consecutive hours but no longer than 7 calendar days following grouting and/or placement of surface protection.

2.0 MATERIALS

- Work Plans;
- Well Development Form;
- Field Logbook;
- Boring Log and Well Completion Diagram for the well;
- Submersible pump, control box, associated equipment, etc;
- Photoionization detector or other appropriate monitoring instrument as specified in site-specific health and safety plan;
- Personal protective equipment and clothing (PPE) as specified in site-specific health and safety plan;
- Flow-through-cell and probes measuring specific conductance, pH, temperature, oxidation/reduction potential, dissolved oxygen, and turbidity;
- Decontamination supplies (SOP 80.1);
- Electric well level indicator and measuring tape;
- Appropriate containers for purged water and other investigation-derived material, as required; and
- Drilling tools for reverse-air circulation development, as appropriate.

3.0 PROCEDURE

3.1 SELECTING METHOD OF DEVELOPMENT

The type of subsurface conditions encountered should determine the method of well development used at a particular site at the Radford Army Ammunition Plant (RFAAP).

When monitoring wells are installed within overburden material, fractured bedrock or karst aquifers producing little sediment, a combination of mechanical surging and pumping (over pumping) or bailing is generally appropriate for well development. In general, over-pumping is the method of pumping the well at a rate higher than recharge occurs. Moving a tight-fitting surge block along the inside of the well screen to create a vacuum completes surging.

When monitoring wells are installed with solution features containing excessive amounts of sediment, reverse-circulation airlifting should be used as the initial step of development. Because reverse-circulation tools airlift methods avoid forcibly exposing the annular space to air, reverse-circulation tools can be run throughout the entire water column in the wells being developed.

After the excessive sediment has been removed by reverse-circulation airlifting, conventional pumping techniques may be used as appropriate to complete the well development.

3.2 DEVELOPMENT AND SAMPLING TIMING

Final development of monitoring wells should not be initiated any sooner than 48 hours after or more than 7 days beyond the final grouting of the well. Pre-development or preliminary development may be initiated before this 48-hour minimum period. Preliminary development may be conducted for open wells or for screened wells after installation of the well screen, casing, and filter pack but before installation of the annular seal. Pre-development is recommended when the natural formation will be used as a filter pack.
Well development should be completed at least 14 days prior to sampling.

3.3 SUMMARY OF PROCEDURES

In general, the following procedure should be followed when developing a well using the pump and surge technique:

1. Prepare the work area outside the well by placing plastic sheeting on the ground to avoid cross-contamination.
2. Calibrate water quality meters (refer to SOP 40.1).
3. Determine the depth to water and total depth of well (refer to SOP 40.2).
4. Calculate the equivalent volume (EV) of water in well to be developed (refer to SOP 30.2).
5. Pump or bail the well to ensure that water flows into it and to remove some of the fine materials from the well. Removal of a minimum of one EV is recommended at this point. The rate of removal should be high enough to stress the well by lowering the water level to approximately one-half its original level.
6. Remove pump or bailer, slowly lower a close-fitting surge block into the well until it rests below the static water level but above the screened interval. (NOTE: The latter is not required in the case of an LNAPL well.)
7. Begin a gentle surging motion along top on-third length of the screen, which will allow any material blocking the screen to break up, go into suspension, and move into the well. Note that development should always begin above or at the top of the screen and move progressively downward to prevent the surge block from becoming sand locked in the well casing. Continue surging for 5-10 minutes, remove surge block, and pump or bail the well, rapidly removing at least one EV.
8. Repeat previous step at successively lower levels within the well screen, until the bottom of the well is reached. As development progresses, successive surging can be more vigorous and of longer duration as long as the amount of sediment in the screen is kept to a minimum.
9. Development should continue until the well development criteria listed in Section 3.1.3 have been achieved.
10. All water removed must be managed as directed by the site investigation plan.

3.3.1 Well Development Criteria

In general, well development should proceed until the following criteria are met:

1. At a minimum, removal of three EV of water from the well.
2. Removal of three times of the amount of fluid (mud and/or water) lost during drilling.
3. Removal of three times the fluid used for well installation.
4. The following indicator parameters should be stabilized as indicated by three successive readings within:
    - ± 0.2 for pH;
    - ±3% for specific conductance;
    - ±10 mV for oxidation/reduction potential;
    - ± 1 degree Celsius for temperature; and
    - ±10% for turbidity and dissolved oxygen (except for wells installed in karst aquifers).
5. Well water is clear to the unaided eye (except for wells installed in karst aquifers).
6. The sediment thickness remaining within the well is less than one percent of the screen length or less than 0.1 ft for screens equal to or less than 10 feet.
7. Site specific factors should be evaluated to determine appropriate well development criteria have been if:
    - Well recharge is so slow that the required volume of water cannot be removed during 48 consecutive hours of development;
    - Water discoloration persists after the required volumetric development; and
    - Excessive sediment remains after the required volumetric development.

3.4 WELL DEVELOPMENT RECORD

Record all data as required on a Well Development Record Form (see example), which becomes a part of the complete Well Record. These data include the following:

- Project name, location;
- Well designation, location;
- Date(s) and time(s) of well installation;
- Static water level from top of well casing before and 24 hours after development;
- Depths and dimensions of the well, the casing, and the screen, obtained from the Well Diagram;
- Water losses and uses during drilling, obtained from the boring log for the well;
- Water contained in the well, obtained from calculations using the depth of the water column and the well radius, plus the radius and height of the filter pack and an assumed 30% porosity;
- Measurements of the following indicator parameters: pH, conductivity, oxidation/reduction potential, temperature, and turbidity before and after development and once during each EV;
- Notes on characteristics of the development water;
- Data on the equipment and technique used for development; and
- Estimated recharge rate and rate/quantity of water removal during development.

Well development records shall be submitted to the COR after the development has been completed.

3.5 INVESTIGATION-DERIVED MATERIAL

Investigation-derived material will be managed in accordance with procedures defined in the work plan addendum for the site being investigated and SOP 70.1.

4.0 MAINTENANCE

Not applicable.

5.0 PRECAUTIONS

Refer to the site-specific health and safety plan.

STANDARD OPERATING PROCEDURE 20.3
WELL AND BORING ABANDONMENT

1.0 SCOPE AND APPLICATION

The purpose of this standard operating procedure (SOP) is to establish the protocols by which all borings and wells will be abandoned. The primary objective of boring or well abandonment activities is to permanently abandon the boring or well so that the natural migration of groundwater or soil vapor is not significantly influenced.

2.0 MATERIALS

- Well abandonment equipment including appropriate grout mixing/placement equipment, and heavy equipment as appropriate (drill rig, crane, backhoe, etc.);
- Pure sodium bentonite powder with no additives (bentonite);
- Bentonite pellets (seal);
- Cement (Portland Type II); and
- Approved source water.

3.0 PROCEDURE

The volume of grout required for borehole or well abandonment should be calculated prior to proceeding with abandonment. These calculations should consider loss of material to the formation, changes in borehole diameter, potential zones of washout, and shrinkage of material. Calculations should be recorded on an abandonment record (see Section 3.1.4).

In general, cement grout should be used for boring and well abandonment per the specifications in Section 3.1 and procedures identified in the following sections. Specialized narrow diameter soil borings (3-inches or less) associated with direct push methods or hand augers may be abandoned using bentonite pellets or chips (see Section 3.5).

Any replacement borings or wells associated with the abandonment should be offset at least 20 feet from any abandoned site in a presumed up- or cross-gradient direction.

3.1 GROUT

Grout used in construction will be composed by weight of the following:

- Type II Portland cement (Type IV Portland Cement if sulfate concentrations are greater than 1,500 ppm);
- Bentonite (2 to 5% dry bentonite per 94-lb sack of dry cement); and
- A maximum of 6 to 7 gallons of approved water per 94-lb sack of cement.

Neither additives nor borehole cuttings will be mixed with the grout. Bentonite will be added after the required amount of cement is mixed with the water.

All grout material will be combined in an aboveground container and mechanically blended to produce a thick, lump-free mixture. The mixed grout will be recirculated through the grout pump before placement.

Grout placement will be performed using a commercially available grout pump and a rigid tremie pipe. Removal and grouting will be accomplished in stages, aquifer by aquifer, sealing the boring from the bottom to ground surface. This will be accomplished by placing a grout pipe to the bottom and pumping grout through the pipe until undiluted grout reaches the bottom of the next higher section of casing or, for the top-most section, until grout flows from the boring at ground surface.

After 24 hours, the abandoned drilling site will be checked for grout settlement. Any settlement will be filled with grout and rechecked 24 hours later. This process will be repeated until firm grout remains at the ground surface.

3.2 BORINGS

The term "borings" as used in this SOP applies to any drilled hole made that is not completed as a well. This includes soil test borings, soil sampling borings, and deep stratigraphic borings. Whether completed to the planned depth or aborted for any reason before reaching that depth, borings will be grouted and will be normally closed within 12 hours.

To achieve an effective seal, the borehole to be abandoned should be free of debris and foreign matter that may restrict the adhesion of the grout to the borehole wall. Borehole flushing with a tremie pipe may be required to remove such materials prior to grouting.

Each boring to be abandoned should be sealed by grouting from the bottom of the boring to the ground surface. This will be accomplished by placing a tremie pipe to the bottom of the borehole and pumping grout through the pipe at a steady rate. The grouting should be completed slowly and continuously to prevent channeling of material. The tremie pipe should be raised when pumping pressure increases significantly or when undiluted grout reaches the surface.

After 24 hours of completing the abandonment, the abandoned boring or well should be checked for any grout settlement. The settlement depression should be filled with grout and rechecked 24 hours later. Grout should be placed with a tremie pipe if the open hole is 15 feet or deeper or if the hole is not dry. Otherwise, the grout may be poured from the surface.

3.3 NARROW BORINGS

Narrow borings, those with diameter less than 3 inches, advanced by hand auger or direct push methods, may be sealed using bentonite pellets or chips rather than a grout mixture. Often times a grout pump is not available to mix the grout when these methods have been used. Bentonite pellets or chips will be poured into the boring from the ground surface. Then bentonite will hydrate by absorbing moisture from the ground; unapproved water should not be added to the boring. After 24 hours, the abandoned boring will be checked, and any grout settlement will be topped off with more bentonite. The process will be repeated until bentonite remains at ground surface unless site condition indicates otherwise.

3.4 WELLS

The following procedure applies to wells aborted before completion and existing wells determined to be ineffective or otherwise in need of closure.

General Considerations

A number of techniques are available for abandoning monitoring wells and other monitoring devices including:

- Abandonment in place by grouting the well screen and casing in place;
- Removal of the well by pulling; and
- Overdrilling.

The particular method used for abandonment should be specified in the work plan addenda developed for a site-specific investigation. Several factors must be considered when selecting the appropriate abandonment technique including well construction, well condition, and subsurface conditions.
In general the preferred method for abandonment of wells is to remove all existing well materials to:

- Reduce the potential for the formation of a vertical conduit to occur at the contact between the casing and annular seal;
- Reduce the potential for well materials interfering with the abandonment procedures; and
- Decrease the potential for reaction between the well materials and grout used for abandonment.

In general, all well materials will be removed during abandonment (including screen and casing) by either pulling out the casing, screen, and associated materials or by overdrilling using a rotary or hollow stem auger drilling procedure.

Abandonment with Well Materials In Place

In the event that it is not possible to remove the casing and screen, the casing and screen will be perforated using a suitable tool. A minimum of four rows of perforations several inches long and a minimum of five perforations per linear foot of casing or screen is recommended.

After the screen and casing have been appropriately perforated, the well should be abandoned by grouting from the bottom of the well to the ground surface using a tremie pipe as described in Section 3.2. The tremie pipe should be raised when pumping pressure increases significantly or when undiluted grout reaches the surface.

After 24 hours of completing the abandonment, the abandoned well should be checked for any grout settlement. The settlement depression should be filled with grout and rechecked 24 hours later. Grout should be placed with a tremie pipe if the open hole is 15 feet or deeper or if the hole is not dry. Otherwise, the grout may be poured from the surface.

Abandonment by Removal

Site conditions permitting, relatively shallow monitoring wells may be successfully abandoned by removal providing that the well is generally good condition and sections of casing (including screen) can be successfully removed with materials intact.

This method of abandonment is generally accomplished by removing (pulling) sections of casing and screen out of the subsurface using a drill rig, backhoe, crane, etc. of sufficient capacity. Materials with lower tensile strength such as polyvinyl chloride (PVC) generally cannot be removed by pulling if they have been appropriately cemented in place.

Once the well materials have been removed from the borehole, the borehole should be abandoned by grouting in the same manner discussed for borings in Section 3.2. If the borehole collapses after removal of well materials, then the borehole should be over drilled to remove all material and then grouted to the surface.

Overdrilling

With this method of abandonment, the well materials are removed by overdrilling (overreaming) the well location. Overdrilling using rotary techniques may be accomplished using an overreaming tool. This tool consists of a pilot bit that is approximately the same size as the inner diameter of well casing and a reaming bit that is slightly larger than the diameter of the borehole. As drilling proceeds, all well materials are destroyed

and returned to the surface. After completion of the overdrilling, the borehole should be immediately grouted with a tremie pipe as described in Section 3.2.

In the case of overburden wells, a hollow stem auger may be used for overdrilling providing that this method of drilling appropriate for the subsurface conditions. The hollow stem auger should be equipped with outward facing carbide-cutting teeth with a diameter 2 to 4 inches larger than the well casing. With this method, the casing guides the cutting head and remains inside the auger. When the auger reaches the bottom of the well boring and the well materials have been removed, the borehole may be grouted with a tremie pipe (Section 3.2) through the augers as the augers are gradually withdrawn.

Considerations for Fractured Bedrock and Karst Wells

Multi-cased wells completed into bedrock as screened wells, open wells, or open-lined wells may be abandoned with the outer casing left in place providing that the integrity of this casing and associated annular seal is good. A cement bond log (acoustic amplitude boring geophysical log) may be used to evaluate the integrity of the casing and annular seal, if the outer casing is to be left in place.

Borings or wells completed in karst zones may be difficult to abandon because of the potential presence of large conduits, which may make it difficult to grout. Where large conduits exist or difficulties are encountered when abandoning a boring or well, fill the portion of the borehole penetrating the solution cavity with inert gravel (quartz, claystone, etc.). Packers can be used to isolate critical intervals for filling with grout above and below these zones.

3.5 RESTORATION

All work areas around the borings or wells abandoned should be restored to a condition essentially equivalent to that before the borings and wells were installed.

3.6 INVESTIGATION-DERIVED MATERIAL

Investigation-derived material should be managed in accordance with the requirements of SOP 70.1 and the work plan addenda associated with the site investigation

3.7 DOCUMENTATION

For each abandoned boring or well, a record should be prepared to include the following as appropriate:

- Project and boring/well designation;
- Location with respect to replacement boring well (if any);
- Open depth of well/annulus/boring prior to grouting;
- Casing or items left in hole by depth, description, composition, and size;
- Copy of the boring log;
- Copy of construction diagram for abandoned well;
- Reason for abandonment;
- Description and total quantity of grout used initially;
- Description and daily quantities of grout used to compensate for settlement;
- Disposition of investigation-derived material;
- Water or mud level prior to grouting and date measured; and
- Remaining casing above ground surface, height above ground surface, size, and disposition of each.

Daily investigation activities at the site related to boring and well abandonment should be recorded in field logbooks as described in SOPs 10.1 and 10.2.

4.0 PRECAUTIONS

Refer to the health and safety plan associated with the Work Plan Addenda and the Master Health and Safety Plan.

STANDARD OPERATING PROCEDURE 20.11
DRILLING METHODS AND PROCEDURES

1.0 SCOPE AND APPLICATION

The use of an appropriate drilling procedure is contingent upon the existing conditions at the project site. The purpose of this standard operating procedure (SOP) is to outline procedures for the various methods of soil and rock drilling identified in the Master Work Plan. In addition it provides procedures for using sampling devices commonly used during soil and rock drilling such as split-barrel sampling, thin walled tube sampling, direct push samplers, and rock coring. For a particular site investigation, the associated work plan addendum will identify the appropriate drilling method and method of sampling, along with proposed sampling depths and intervals and any special procedures or methods.

2.0 MATERIALS

The following types of materials are generally appropriate for drilling:

2.1 SPLIT-BARREL SAMPLING

- Split barrel sampler;
- Borehole logging materials per SOP 10.3 and sampling equipment and materials, as appropriate per SOP 30.1;
- Containers to manage investigation-derived material per SOP 70.1; and
- Decontamination supplies and equipment per SOP 80.1.

2.2 THIN WALLED TUBE SAMPLING

- Thin walled tubes;
- Sealing materials for sample such as sealing wax, metal disks, wood disks, tape, cheesecloth, caps, etc;
- Borehole logging materials per SOP 10.3 and sampling equipment and materials, as appropriate per SOP 30.1;
- Containers to manage investigation-derived material per SOP 70.1; and
- Decontamination supplies and equipment per SOP 80.1.

2.3 DIRECT PUSH SAMPLING

- Direct push unit with hydraulic ram, hammer, etc;
- Sample collection devices, associated equipment and expendable supplies such as sample liners, sample retainers, appropriate lubricants, etc;
- Hollow extension rods;
- Auxiliary tools for handling, assembling, and disassembling tools and samplers;
- Borehole logging materials per SOP 10.3 and sampling equipment and materials, as appropriate per SOP 30.1;

- Containers to manage investigation-derived material per SOP 70.1; and
- Decontamination supplies and equipment per SOP 80.1.

2.4 HOLLOW-STEM AUGER DRILLING

- Drill rig and associated equipment;
- Hollow stem auger assemblies for drilling to appropriate depth including auger heads, drive assembly, pilot assembly, and hollow-stem auger sections;
- Auxiliary devices such as wrenches, auger forks, hoisting hooks, swivels, and adaptors;
- Borehole logging materials per SOP 10.3 and sampling equipment and materials, as appropriate per SOP 30.1;
- Containers to manage investigation-derived material per SOP 70.1; and
- Decontamination supplies and equipment per SOP 80.1.

2.5 DIRECT AIR ROTARY DRILLING

- Drill rig with rotary table and Kelly or top-head drive unit;
- Drill rods, bits, and core barrels (as appropriate);
- Casing;
- Sampling devices and equipment, as appropriate;
- Air compressor and filters, pressure lines, discharge hose, swivel, dust collector, and air-cleaning device (cyclone separator);
- Auxiliary tools for handling, assembling, and disassembling tools and samplers;
- Borehole logging materials per SOP 10.3 and sampling equipment and materials, as appropriate per SOP 30.1;
- Containers to manage investigation-derived material per SOP 70.1; and
- Decontamination supplies and equipment per SOP 80.1.

2.6 DRILL-THROUGH CASING DRIVER

- Drill rig equipped with a mast-mounted, percussion driver;
- Casing, drill rods, and drill bits or hammers;
- Air compressor and filters, pressure lines, discharge hose, swivel, dust collector, and air-cleaning device (cyclone separator);
- Sampling devices and equipment, as appropriate;
- Auxiliary tools for handling, assembling, and disassembling tools and samplers;
- Welding equipment and materials for installation of casing;
- Borehole logging materials per SOP 10.3 and sampling equipment and materials, as appropriate per SOP 30.1;
- Containers to manage investigation-derived material per SOP 70.1; and

- Decontamination supplies and equipment per SOP 80.1.

2.7 DIRECT WATER-BASED ROTARY DRILLING

- Drill rig with derrick, rotary table and Kelly or top-head drive unit;
- Drill rods, bits, and core barrels (as appropriate);
- Casing;
- Water based drilling fluid, with approved additives as appropriate;
- Mud tub, suction hose, cyclone de-sander(s), drilling fluid circulation pump, pressure hose, and swivel;
- Auxiliary tools for handling, assembling, and disassembling tools and samplers;
- Borehole logging materials per SOP 10.3 and sampling equipment and materials, as appropriate per SOP 30.1;
- Containers to manage investigation-derived material per SOP 70.1.
- Decontamination supplies and equipment per SOP 80.1.

2.8 DIRECT ROTARY WIRELINE-CASING ADVANCEMENT DRILLING

- Drill rig with either hollow spindle or top-head drive;
- Drill rods, coring or casing bits, overshot assembly, pilot bit, and core barrel;
- Water based drilling fluid, with approved additives as appropriate;
- Mud tub, suction hose, drilling fluid circulation pump, pressure hose, and swivel;
- Auxiliary tools for handling, assembling, and disassembling tools and samplers;
- Borehole logging materials per SOP 10.3 and sampling equipment and materials, as appropriate per SOP 30.1;
- Containers to manage investigation-derived material per SOP 70.1; and
- Decontamination supplies and equipment per SOP 80.1.

2.9 DIAMOND CORE DRILLING

- Direct rotary drill rig and associated equipment (see Sections 2.4, 2.5 or 2.6);
- Core barrels and core bits;
- Core lifters;
- Core boxes, engineers scale, permanent marking pen, and camera for photographing cores;
- Auxiliary tools for handling, assembling, and disassembling tools and samplers;
- Borehole logging materials per SOP 10.3 and sampling equipment and materials, as appropriate per SOP 30.1;
- Containers to manage investigation-derived material per SOP 70.1; and
- Decontamination supplies and equipment per SOP 80.1.

3.0 PROCEDURES

3.1 PENETRATION TEST AND SPLIT-BARREL SAMPLING OF SOILS

The following general procedure may be followed as outlined in ASTM Standard Test Method D 1586.

1. Advance the boring to the desired sampling depth using an appropriate drilling method (see sections below) and remove excessive cuttings from the borehole.
2. Attach the split-barrel sampler to the sampling rods and lower into the borehole. Do not allow the sampler to drop onto the soil to be sampled.
3. Position the hammer above and attach the anvil to the top of the drilling rods.
4. Rest the dead weight of the sampler, rods, anvil, and drive weight on the bottom of the boring and apply a seating blow. If excessive cuttings are encountered at the bottom of the borehole, remove the sampler and rods from borehole and remove the cuttings.
5. Mark the drill rods in three successive 6-inch increments so that the advance of the sampler can be observed.
6. Drive the sampler with blow from the 140 pound hammer and count the number of blows applied in each 6-inch increment until:
   a. Fifty (50) blows have been applied during one of the three 6-inch increments.
   b. A total of 100 blows have been applied.
   c. There is no observed advance of the sampler during the application of 10 successive blows of the hammer.
7. The sampler is advanced the complete 18-inches without the limiting blow counts occurring as described above.
8. Record the number of blows that is required to achieve each 6-inch increment of penetration or fraction of this increment on the boring.
   a. The first 6 inches is considered the seating driver.
   b. The sum of the second and third 6-inch penetration intervals is termed the “standard penetration resistance” or “N-value.”
   c. If the sampler is driven less than 18 inches as discussed in No. 6, then the number of blow for each partial increment will be recorded.
   d. For partial increments, the depth of penetration should be recorded to the nearest 1-inch on the boring log.
   e. If the sampler advances below the bottom of the boring under the weight of rods (static) and/or hammer, then this information will be recorded on the boring log.
9. The raising and dropping of the 140 pound hammer may be accomplished by:
   a. Using a trip, automatic, or semi-automatic hammer drop system that lifts the hammer and allows it to drop 30± 1 inches.
   b. Using a cathead shall be essentially free of rust, oil, or grease and have a diameter in the range of 6 to 10 inches. The cathead should be operated at a minimum speed of rotation of 100 revolutions per minute. No more than 2-1/4 rope turns on the cathead may be used when conducting the penetration test.

10. For each hammer blow, a 30-inch lift and drop shall be used.
11. After completing the penetration test, retrieve the sampler and open. Record the percent recovery or the length of sample recovered. Following the procedures outlined in SOP 30.1 when collecting environmental soil samples.
12. Borehole logging should be completed per SOP 10.3.
13. Split-barrel samples must be decontaminated before and after each use per the requirements of SOP 80.1.

3.2 THIN WALLED TUBE SAMPLING

The following general procedure may be followed for collection of relatively undisturbed, thin walled tube samples (e.g., Shelby tube) as outlined in ASTM Standard Practice D 1587.

1. Clean out the borehole to targeted sampling depth using most appropriate method, which avoids disturbing the material to be sampled. If groundwater is encountered, maintain the liquid level in the borehole at or above the groundwater level during sampling.
2. Place the sample tub so that its bottom rests on the bottom of the borehole.
3. Advance the sampler without rotation by a continuous relatively rapid motion.
4. Determine the length of the advance by the resistance and condition of the formation, the length of the advance should never exceed 5 to 10 diameters of the tube in sands and 10 to 15 diameters of the tube in clay.
5. When the formation is too hard for push type of sampling, the tube may be driven or the practice used for ring-lined barrel sampling may be used per ASTM Standard D 3550. When a sample is driven, the weight and fall of the hammer must be recorded along with the penetration achieved.
6. The maximum length of sample advance will be no longer than the sample-tube length minus an allowance for the sample head and a minimum of 3-inches for sludge-end cuttings.
7. Upon removal of the tube, measure the length of the sample in the tube. Remove the disturbed material in the upper end of the tube and re-measure the sample length.
8. Remove at least one-inch of material from the lower end of the tube for soil description and identification per SOP 10.3. Measure the overall sample length. Seal the lower end of the tube. If directed, the material from the end of the tube will not be removed for soil identification and description; in this case the tube will be sealed promptly.
9. Prepare sample labels and affix (or markings) on the tube.

3.3 DIRECT PUSH SOIL BORING

The following general procedures outlined in this section may be followed as described in ASTM Standard Test Method D 6282.

General considerations for this method include the following:

- A variety of direct push drive systems may be used to advance soil borings based on the intended sampling depths and subsurface conditions and include the following:

Shallower Depths and Less Difficult Conditions

- Percussive driving systems – use hydraulically operated hammers and mechanically operated hammers.
- Static push drive systems – use hydraulic rams to apply pressure and exert static pull (e.g., cone penetrometer systems).
- Vibratory/sonic systems – use a vibratory device, which is attached to the top of the sampler extension rods.

Greater Depths and More Difficult Conditions

- Sonic or resonance drilling systems – use a high power vibratory system to advance larger diameter single or dual tube systems.
- Rotary drilling equipment – use hydraulic system of drill rig for direct push.

- The equipment used for direct push must be capable of apply sufficient static force, or dynamic force, or both, to advance the sampler to the required depth of collection. Additionally, this equipment must have adequate retraction force to remove the sampler and extension/drive rods once the sample has been collected.
- Avoid using excessive down pressure when advancing the drilling tools/sampler. Excessive pressure may cause the direct push unit to offset from the boring location and may damage drilling tools and samplers.
- Sample liners should be compatible with the material being sampled and the type of analysis to be conducted on the sample. Sealing of liners for submittal to the laboratory for physical testing should be accomplished according to ASTM Standard D 4220 (Standard Practice for Preserving and Transporting Soil Samples).
- The general procedure for completing direct push soil borings is the following:

1. Stabilize direct push unit and raise mast at desired location.
2. Attach the hammer assembly to the drill head if not permanently attached. Attach the anvil assembly in the prescribed manner, slide the direct push unit the position over the borehole, and ready the tools for insertion.
3. Inspect the direct push tools before and after use. Decontaminate all down hole tools before and after use per SOP 80.1.
4. Inspect drive shoes for damaged cutting edges, dents or thread failures and these conditions could cause loss of sample recovery and slow the rate of advancement.
5. Assemble samplers and install where required, install sample retainers where needed, and install and secure sampler pistons to ensure proper operation where needed (see Steps 14 through 20 for the various sampler assembly procedures, etc.).
6. After sampler has been appropriately installed (see Steps 14 through 20 for installation procedures, etc.) advance the boring to the target sampling depth using an appropriate direct push technique, as identified above under general considerations.
7. Collect the soil sample from the target sampling depth using one of the methods identified in Steps 14 through 20.
8. Retrieve the sampler and appropriately process the soil sample as identified in Steps 14 through 20 below and in SOP 30.1.
9. Log the borehole per the requirements of SOP 10.3.
10. If collecting another soil sample, decontaminate the sampler for reuse per the requirements of SOP 80.1 or use another decontaminated sampler.

11. Appropriately manage investigation-derived material (discarded samples, decontamination fluids, etc.) per SOP 70.1.
12. Upon completion of the boring and collection of the desired soil samples, abandon the boring per the requirements of SOP 20.2.
13. The following single tube sampling systems (generally piston rod) may be used to collect soil samples (see Steps 14 through 16 below):
    a. Open Solid Barrel Sampler;
    b. Closed Solid Barrel Sampler (e.g. Geoprobe Macro-Core® Piston Rod Sampler); and
    c. Standard Split Barrel Sampler (see Section 3.1).
14. The following two tube sampling systems may be used to collect soil samples (see Steps 17 through 20 below):
    a. Split Barrel Sampler;
    b. Thin Wall Tubes;
    c. Thin Wall Tube Piston Sampler; and
    d. Open Solid Barrel Samplers.
15. Sampling with the single tube, open solid barrel sampler:
    a. Attach the required liner to the cutting shoe by insertion into the machined receptacle are or by sliding over the machined tube.
    b. Insert the liner and shoe into the solid barrel and attach the shoe.
    c. Attach the sampler head to the sampler barrel.
    d. Attach the sampler assembly to the drive rod and the drive head to the drive rod.
    e. Position the sampler assembly under the hammer anvil and advance the sampler assembly into the soil at a steady rate slow enough to allow the soil to be cut by the shoe and move up into the sample barrel.
    f. At the completion of the sampling interval, removal the sampler from the borehole. Remove the filled sampler liner from the barrel by unscrewing the shoe. Cap the liner for laboratory testing or split open for field processing (see SOP 30.1).
    g. Log the borehole per the requirements of SOP 10.3.
16. Sampling with the closed, solid barrel sampler (e.g., Macro-Core® sampler).
    a. Insert or attach the sample liner to the shoe and insert the assembly into the solid barrel sampler. Install the sample, retaining basket, if desired.
    b. Attach the latch coupling or sampler head to the sampler barrel, and attach the piston assembly with point and "O" rings if free water is present, to the latching mechanism.
    c. Insert the piston or packer into the liner to its proper position so that the point leads the sampler shoe. Set latch, charge packer, or install locking pin, and attach assembled sampler to drive rod.
    d. Add drive head and position under the hammer anvil. Apply down pressure, and hammer if needed, to penetrate the soil strata above the targeted sampling interval.
    e. When the sampling interval is reached, insert the piston latch release and recovery tool, removing the piston, or insert the locking pin removal/extension rods through the drive rods, turn counter clockwise, and remove the piston locking pin so the piston can float on top of the sample, or release any other piston holding device.
    f. Direct push or activate the hammer to advance the sampler the desired interval.

g. Retrieve the sampler from the borehole by removing the extension/drive rods. Remove the shoe, and withdraw the sample line with sample for processing (see SOP 30.1).

h. Clean and decontaminate the sampler, reload as described above and repeat the same procedure for collection of addition samples.

i. Log the borehole per the requirements of SOP 10.3.

17. Sampling with standard split barrel (split spoon) sampler generally consists of the following:

a. Attach the split barrel sampler to an extension rod or drill rod.

b. Using a mechanical or hydraulic hammer drive the ampler into the soil the desired interval. The maximum interval that should be driven is equal to the sample chamber length of the split barrel sampler, which is either 18-inches or 24-inches.

c. Retrieve the sampler from the borehole by removing the extension/drive rods.

d. Split the sampler open for field processing (see SOP 30.1).

e. Clean and decontaminate the sampler (SOP 80.1), re-attach and repeat the same procedure for collection of additional samples.

f. Log the borehole per the requirements of SOP 10.3.

18. Sampling with a two tube, split barrel sampler generally consists of the following:

a. Assemble the outer casing with the drive shoe on the bottom, attach the drive head to the top of the outer casing, and attach the sampler to the extension rods.

b. Connect the drive head to the top of the sampler extension rods, and insert the sampler assembly into the outer casing.

c. The cutting shoe of the sampler should contact the soil ahead of the outer casing to minimize sample disturbance.

d. The sample barrel should extend a minimum of 0.25 inches ahead of the outer casing.

e. Mark the outer casing to identify the required drive length, position the outer casing and sampler assembly under the drill head.

f. Move the drill head downward to apply pressure on the tool string. Advance the casing assembly into the soil at a steady rate, which is slow enough to allow the soil to be cut by the shoe and move up inside the sample barrel.

g. Occasional hammer action during the push may assist recovery.

h. If smooth push advancement is not possible because of subsurface conditions, use the hammer to advance the sampler.

i. Stop the application of pressure or hammering when target interval has been sampled. Move the drill head off the drive head. Attach a pulling device to the extension rods or position the hammer bail and retrieve the sampler from the borehole.

j. At the surface, remove the sampler from the extension rods and process the sample per Section 3.01 and SOP 30.1.

k. Log the borehole per the requirements of SOP 10.3.

19. Sampling with a two tube, thin wall tube sampler generally consists of the following:

a. Attach the tube to the tube head using removable screws.

b. Attach the tube assembly to the extension rods and position at the base of the outer casing shoe protruding a minimum of 0.25 inches to contact the soil ahead of the outer casing.

c. Advance the tube with or without the outer casing at a steady rate.

d. After completing the sampling interval, let the tube remain stationary for one minute. Rotate the tube slowly two revolutions to shear off the sample.

e. Remove the tube from the borehole and measure the recovery, and log the borehole per the requirements of SOP 10.3.

f. For field processing, extrude the sample from the tube sampler and process per SOP 30.1. Alternatively, the tube may be sealed and shipped to the laboratory.

20. Sampling with two tube, thin wall tube, piston sampler generally consists of the following:

    a. Check the fixed piston sampling equipment for proper operation of the cone clamping assembly and the condition of the "O" rings.

    b. Slide the thin wall tube over the piston, and attach it to the tube head. Position the piston at the sharpened end of the thin wall tube just above the sample relief bend.

    c. Attach the tube assembly to the extension rods and lower the sampler into position through the outer casing. Install the actuator rods through the extension rod, and attach to the actuator rod in the sampler assembly.

    d. Attach a holding ring to the to top of the actuator rod string and hook the winch cable or other hook to the holding ring to hold the actuator rods in a fixed position.

    e. Attach the pushing fork to the drill head/probe hammer and slowly apply downward pressure to the extension rods advancing the thin wall tube over the fixed piston into the soil for the length of the sampling interval.

    f. After completing the sampling interval, let the tube remain stationary for one minute. Rotate the tube slowly one revolution to shear off the sample.

    g. Remove the tube sampler from the borehole and measure the recovery, and log the borehole per the requirements of SOP 10.3.

    h. For field processing, extrude the sample from the tube sampler and process per SOP 30.1.

21. Sampling with an two tube, open solid barrel sampler generally consists of the following:

    a. This sampling technique may be used when soil conditions prevent advancement of a split barrel sampler or advancement of an outer casing.

    b. The solid, single, or segmented barrel sampler requires the use of a liner.

    c. Use sampler in advance of outer casing when this casing cannot be advanced.

    d. Follow the procedures outlined for two tube, split barrel sampling.

3.4 HOLLOW-STEM AUGER DRILLING

The following general procedure may be followed as outlined in ASTM Standard Guide D 5784.

1. Stabilize drill rig and raise mast at desired location.
2. Attach an initial assembly of hollow-stem auger components (hollow stem auger, hollow auger head, center rod and pilot assembly, as appropriate) to the rotary drive of the drill rig.
3. Push the auger assembly below the ground surface and initiate rotation at a low velocity.
4. Decontamination of auger head may be necessary after this initial penetration if this surface soil is contaminated.
5. Continue drilling from the surface, usually at a rotary velocity of 50 to 100 rotations per minute to the depth where sampling or in-situ testing is required or until the drive assembly is within approximately 6- to 18 inches of the ground surface.
6. As appropriate, collect a soil sample from the required depth interval. The sample may be conducted by

a. Removing the pilot assembly, if used, and inserting and driving a sampler through the hollow stem auger of the auger column; or

b. Using a continuous sampling device within the lead auger section, where the sampler barrel fills with material as the auger is advanced.

7. Additional sections of hollow stems augers may be added to drill to a greater depth. After these auger sections are added, rotation of the hollow-stem auger assembly may be resumed.

8. When drilling through material suspected of being contaminated, the installation of single or multiple (nested) outer casings may be required to isolate zones suspected contamination (see SOP 20.1). Outer casings may be installed in a pre-drilled borehole or using a method in which casing is advanced at the same of drilling.

   Monitoring wells or piezometers may be installed using hollow-stem augers by:

   a. Drilling with or without sampling to the target depth.

   b. Removal of the pilot assembly, if used, and insertion of the monitoring well (or piezometer) assembly.

   c. The hollow stem auger column should be removed incrementally as the monitoring well (or piezometer) completion materials are placed (see SOP 20.1 for grouting).

9. If materials enter the bottom of the auger hollow stem during the removal of the pilot assembly, it should be removed with a drive sampler or other appropriate device.

10. If sampling or *in-situ* testing is not required during completion of the boring, the boring may be advanced with an expendable knock out plate or plug of an appropriate material instead of a pilot assembly.

11. Drill cuttings should be appropriately controlled and contained as IDM per SOP 70.1. It may be necessary to drill through a hole of sheet of plywood or similar material to prevent cuttings from contacting the ground surface.

12. The hollow-auger assembly and sampling devices must be decontaminated before and after each use per the methods specified in SOP 80.1.

13. Borehole logging should be completed per SOP 10.3.

14. Borehole abandonment, when required, should be conducted according to SOP 20.3.

3.5 DIRECT AIR ROTARY DRILLING

The following general procedure may be followed as outlined in ASTM Standard Guide D 5784.

1. Stabilize drill rig and raise mast at desired location. Appropriately position the cyclone separator and seal it to the ground surface considering the prevailing wind direction (exhaust).

2. Establish point for borehole measurements.

3. Attach an initial assembly of a bit, down hole hammer, or core barrel with a single section of drill rod, below the rotary table or top-head drive unit, with the bit placed below the top of the dust collector.

4. Activate the air compressor to circulate air through system.

5. Initiate rotation of bit.

6. Continue with air circulation and rotation of the drill-rod column to the depth where sampling or in-situ testing is required or until the length of the drill rod section limits further penetration.

7. Monitor air pressure during drilling operations. Maintain low air pressure at bit to prevent fracturing of surrounding material.

8. Stop rotation and lift the bit slightly off the bottom of the hole to facilitate removal of drill cuttings and continue air circulation until the drill cuttings are removed from the borehole annulus.

9. Open reaching a desired depth of sampling, stop the air circulation and rest bit on bottom of hole to determine the depth. Record the borehole depth and any resultant caving in. If borehole caving is apparent set a decontaminated casing to protect the boring.
10. When sampling, remove the drill rod column from the borehole or leave the drill rod assembly in place if the sampling can be performed through the hollow axis of the drill rods and bit.
11. Compare the sampling depth to clean-out depth by first resting the sampler on the bottom of the hole and compare that measurement with the clean-out depth measurement.
12. If bottom-hole contamination is apparent (indicated by comparison of sample depth to clean-out depth), it is recommended that the minimum depth below the sampler/bit be 18 inches for testing. Record the depth of sampling or in-situ testing and the depth below the sampler/bit.
13. The procedure described in Steps 8 through 12 should be conducted for each sampling or testing interval.
14. Drilling to a greater depth may be accomplished by attaching an additional drill rod section to the top of the previously advanced drill-rod column and resuming drilling operations as described above.
15. When drilling through material suspected of being contaminated, the installation of single or multiple (nested) outer casings may be required to isolate zones suspected contamination (see SOP 20.1 for grouting requirements). Outer casings may be installed in a pre-drilled borehole or using a method in which casing is advanced at the same of drilling.
16. Monitoring wells or piezometers may be installed by:
    a. Drilling with or without sampling to the target depth.
    b. Removal of the drill rod assembly and insertion of the monitoring well (or piezometer) assembly.
    c. Addition of monitoring well (or piezometer) completion materials (see SOP 20.1).
17. Drill cuttings should be appropriately controlled and contained as IDM per SOP 70.1.
18. The drill rod assembly, sampling devices, and other drilling equipment contacting potentially contaminated material must be decontaminated before and after each use per the methods specified in SOP 80.1.
19. Borehole logging should be completed per SOP 10.3.
20. Borehole abandonment, when required, should be conducted according to SOP 20.3

3.6 DRILL-THROUGH CASING DRILLING

The following general procedure may be followed as outlined in ASTM Standard Guide D 5872.

1. Stabilize drill rig and raise mast at desired location. Appropriately position the cyclone separator and seal it to the ground surface considering the prevailing wind direction (exhaust).
2. Establish point for borehole measurements.
3. Attach an initial assembly of a bit or down hole hammer with a single section of drill rod and casing to the top-head drive unit.
4. Activate the air compressor to circulate air through system.
5. Drilling may be accomplished by
    a. Method 1- the casing will fall, or can be pushed downward behind the bit.
    b. To drill using Drive the casing first followed by drilling out the plug inside the casing.
    c. Method 2 - Advancing the casing and bit as a unit, with the drill bit or hammer, extending up to 12-inches below the casing.
6. Method 3 - Under reaming method where bit or hammer pens a hole slightly larger than the casing so that Method 1, drive the casing first and drill out the plug in the casing by moving the bit or hammer beyond

the casing and then withdrawing it into the casing. Air exiting the bit will remove the cuttings up the hole. Separate cuttings from the return air with a cyclone separator or similar device.

7. To drill using Method 2, advance casing and bit as unit with the bit or hammer extending up to 12-inches beyond the casing depending on the conditions. While drilling, occasionally stop the casing advancement, retract the bit or hammer inside the casing to clear and maintain air circulation to clear cuttings.
8. To drill using Method 3, use a special down hole bit or hammer to open a hole slightly larger than the outside diameter of the casing so that the casing will fall or can be pushed downward immediately behind the bit. After advancing the casing, retract the radial dimension of the drill bit to facilitate removal of the down hole bit or hammer and drill tools inside the casing. Cuttings are removed from the borehole with the air that operates the bit or hammer and can be separated from the air with a cyclone separator or similar device.
9. Monitor air pressure during drilling operations. Maintain low air pressure at bit or hammer to prevent fracturing of surrounding material.
10. Continue air circulation and rotation of the drill rod column until drilling is completed to the target depth (for sampling, in-situ sampling, etc.) or until the length of the drill-rod section limits further penetration.
11. Stop rotation and lift bit or hammer slightly off the bottom of the hole to facilitate removal of drill cuttings and continue air circulation until the drill cuttings are removed from the borehole annulus.
12. After reaching a desired depth of sampling, stop the air circulation and rest the bit on bottom of hole to determine the depth. Record the borehole depth and any resultant caving in. If borehole caving is apparent set a decontaminated casing to protect the boring.
13. When sampling, remove the drill rod column from the borehole. Compare the sampling depth to clean-out depth by first resting the sampler on the bottom of the hole and compare that measurement with the clean-out depth measurement.
14. If bottom-hole contamination is apparent (indicated by comparison of sample depth to clean-out depth), it is recommended that the minimum depth below the sampler/bit be 18 inches for testing. Record the depth of sampling or in-situ testing and the depth below the sampler/bit.
15. The procedure described in Steps 11 through 14 should be conducted for each sampling or testing interval.
16. Drilling to a greater depth may be accomplished by attaching an additional drill rod section and casing section to the top of the previously advanced drill-rod column/casing and resuming drilling operations as described above.
17. Monitoring wells or piezometers may be installed by:
    a. Casing advancement in increments, with or without sampling to the target depth.
    b. Removal of the drill rods and the attached drill bit while the casing is temporarily left in place to support the borehole wall.
    c. Insertion of the monitoring well (or piezometer) assembly.
    d. Addition of monitoring well (or piezometer) completion materials (see SOP 20.1).
18. Drill cuttings should be appropriately controlled and contained as IDM per SOP 70.1.
19. The drill rod assembly, casing, sampling devices, and other drilling equipment contacting potentially contaminated material must be decontaminated before and after each use per the methods specified in SOP 80.1.
20. Borehole logging should be completed per SOP 10.3.
21. Borehole abandonment, when required, should be conducted according to SOP 20.3.

3.7 DIRECT WATER-BASED ROTARY DRILLING

The following general procedure may be followed as outlined in ASTM Standard Guide D 5783.

1. Stabilize drill rig and raise mast at desired location. Appropriately position the mud tub and install surface casing and seal at the ground surface.
2. Establish point for borehole measurements.
3. Attach an initial assembly of a bit or core barrel with a single section of drill rod, below the rotary table or top-head drive unit, with the bit placed with the top of the surface casing.
4. Activate the drilling-fluid circulation pump to circulate drill fluid through the system.
5. Initiate rotation of bit and apply axial force to bit.
6. Document drilling conditions and sequence (fluid loss, circulation pressures, depths of lost circulation, etc.) as described in SOP 10.3.
7. Continue with drill fluid circulation as rotation and axial force are applied to the bit until drilling to the depth
    a) Where sampling or in-situ testing is required;
    b) Until the length of the drill rod section limits further penetration; or
    c) Until core specimen has completely entered the core barrel (when coring) or blockage has occurred.
8. Stop rotation and the lift bit slightly off the bottom of the hole to facilitate removal of drill cuttings and continue fluid circulation until the drill cuttings are removed from the borehole annulus.
9. After reaching a desired depth of sampling, stop the fluid circulation and rest the bit on bottom of hole to determine the depth. Record the borehole depth and any resultant caving in. If borehole caving is apparent set a decontaminated casing to protect the boring.
10. When sampling, drill rod removal is not necessary if the sampling can be performed through the hollow axis of the drill rods and bit.
11. Compare the sampling depth to clean-out depth by first resting the sampler on the bottom of the hole and compare that measurement with the clean-out depth measurement.
12. If bottom-hole contamination is apparent (indicated by comparison of sample depth to clean-out depth), it is recommended that the minimum depth below the sampler/bit be 18 inches for testing. Record the depth of sampling or in-situ testing and the depth below the sampler/bit.
13. The procedure described in Steps 8 through 11 should be conducted for each sampling or testing interval.
14. Drilling to a greater depth may be accomplished by attaching an additional drill rod section to the top of the previously advanced drill-rod column and resuming drilling operations as described above.
15. When drilling through material suspected of being contaminated, the installation of single or multiple (nested) outer casings may be required to isolate zones suspected contamination (see SOP 20.1 for grouting requirements). Outer casings may be installed in a pre-drilled borehole or using a method in which casing is advanced at the same of drilling.
16. Monitoring wells or piezometers may be installed using hollow-stem augers by:
    a. Drilling with or without sampling to the target depth.
    b. Removal of the drill rod assembly and insertion of the monitoring well (or piezometer) assembly.
    c. Addition of monitoring well (or piezometer) completion materials (see SOP 20.1).
17. Drill cuttings and fluids should be appropriately controlled and contained as IDM per SOP 70.1.

18. The drill rod assembly, sampling devices, and other drilling equipment contacting potentially contaminated material must be decontaminated before and after each use per the methods specified in SOP 80.1.
19. Borehole logging should be completed per SOP 10.3.
20. Borehole abandonment, when required, should be conducted according to SOP 20.3.

3.8 DIRECT ROTARY WIRELINE CASING ADVANCEMENT DRILLING

The following general procedure may be followed as outlined in ASTM Standard Guide D 5876.

1. Stabilize drill rig and raise mast at desired location. Appropriately position the mud tub (for water based rotary) and install surface casing and seal at the ground surface.
2. Record the hole depth by knowing the length of the rod-bit assemblies and comparing its position relative to the established surface datum.
3. Attach an initial assembly of a lead drill rod and a bit or core barrel below the top-head drive unit, with the bit placed with the top of the surface casing.
4. Activate the drilling-fluid circulation pump to circulate drill fluid through the system.
5. Initiate rotation of bit and apply axial force to bit.
6. Document drilling conditions and sequence (fluid loss, circulation pressures, depths of lost circulation, down feed pressures etc.) as described in SOP 10.3.
7. In general, the pilot bit or core barrel can be inserted or removed at any time during the drilling process and the large inside diameter rods can act as a temporary casing for testing or installation of monitoring devices.
8. Continue with drill fluid circulation as rotation and axial force are applied to the bit until drilling to the depth
    a) Where sampling or in-situ testing is required;
    b) Until the length of the drill rod section limits further penetration; or
    c) Until core specimen has completely entered the core barrel (when coring) or blockage has occurred.
9. Stop rotation and lift the bit slightly off the bottom of the hole to facilitate removal of drill cuttings and continue fluid circulation until the drill cuttings are removed from the borehole annulus.
10. After reaching a desired depth of sampling, stop the fluid circulation and rest the bit on bottom of hole to determine the depth. Record the borehole depth and any resultant caving in. If borehole caving is apparent set a decontaminated casing to protect the boring.
11. When sampling, drill rod removal is not necessary if the sampling can be performed through the hollow axis of the drill rods and bit.
12. Compare the sampling depth to clean-out depth by first resting the sampler on the bottom of the hole and compare that measurement with the clean-out depth measurement.
13. If bottom-hole contamination is apparent (indicated by comparison of sample depth to clean-out depth), it may be necessary to further clean the hole by rotary recirculation.
14. Continuous sampling may be conducted with a soil core barrel or rock core barrel (see Section 1.7).
15. The pilot bit or core barrel may need to be removed during drilling such as when core barrels are full or there is evidence of core blocking. Before the drill string is reinserted, the depth of the boring should be rechecked to evaluate hole quality and determine whether casing may be required.

16. Water testing may be performed in consolidated deposits by pulling back on the drill rods and passing inflatable packer(s) with pressure fitting to test the open borehole wall (see ASTM Standards D 4630 and D 4631).
17. Drilling to a greater depth may be accomplished by attaching an additional drill rod section to the top of the previously advanced drill-rod column and resuming drilling operations as described above.
18. When drilling through material suspected of being contaminated, the installation of single or multiple (nested) outer casings might be required to isolate zones suspected contamination (see SOP 20.1 for grouting requirements). Outer casings may be installed in a pre-drilled borehole or using a method in which casing is advanced at the same of drilling.
19. Monitoring wells or piezometers may be installed by:
    a. Drilling with or without sampling to the target depth.
    b. Removal of the pilot bit or core barrel and insertion of the monitoring well (or piezometer) assembly.
    c. Addition of monitoring well (or piezometer) completion materials (see SOP 20.1).
20. Drill cuttings and fluids should be appropriately controlled and contained as IDM per SOP 70.1.
21. The drill rod assembly, sampling devices, and other drilling equipment contacting potentially contaminated material must be decontaminated before and after each use per the methods specified in SOP 80.1.
22. Borehole logging should be completed per SOP 10.3.
23. Borehole abandonment, when required, should be conducted according to SOP 20.3.

3.9 DIAMOND CORE DRILLING

The following general procedure may be followed as outlined in ASTM Standard Practice D 2113.

1. Use core-drilling procedures, such as the water-rotary drilling method outlined in Section 3.6.
2. Seat the casing on bedrock or firm formation to prevent raveling of the borehole and to prevent loss of drilling fluid. Level the formation that the casing will be seated on as needed.
3. Begin core drilling using an N-size double-tube, swivel-type core barrel or other approved size or type. Continue core drilling until core blockage occurs or until the net length of the core has been drilled.
4. Remove the core barrel from the borehole, and dis-assemble the core barrel as necessary to remove the core.
5. Reassemble the core barrel and return it to hole.
6. Continue core drilling.
7. Place the recovered core in the core box with the upper (surface) end of the core at the upper-left corner of the core box. Wrap soft or friable cores, etc. as needed or required. Use spacer blocks or slugs properly marked to indicate any noticeable gap in recovered core that might indicate a change or void in the formation. Fit fracture, bedded, or jointed pieces of core together as they naturally occurred.
8. The core within each completed box should be photographed after core surface has been cleaned or peeled, as appropriate, and wetted. Each photo should be in sharp focus and contain a legible scale in feet and tenths of feet (or metric if appropriate). The core should be oriented so that the top of the core is at the top of the photograph. A color chart should be included in the photograph frame as a check on photographic accuracy. The inside lid of the box should also be shown.
9. The inside of the box lid should be labeled at a minimum with the facility name, project name, boring number, box number, and core interval.

10. A preliminary field log of the core must be completed before the core box has been packed for transport (see SOP 10.3). Detailed logging may be conducted at a later time providing the core is appropriately handled and transported.
11. Four levels of sample protection may be used depending on character of the rock and the intended use of the rock core including:
    a. *Routine care* – for rock cored in 5 to 10 foot runs. Consists of placing in structurally sound boxes. Lay flat tubing may be used prior to placing the core.
    b. *Special care* – for rock samples to be tested that are potentially moisture sensitive, such as shale. This care consists of sealing with a tight fitting wrapping of plastic film and application of wax at the ends of the sample.
    c. *Critical care* – for rock samples that may be sensitive to shock and vibration and/or temperature. Protect by encasing each sample in cushioning material, such as sawdust, rubber, polystyrene, foam, etc. A minimum one-inch thick layer of cushioning material should be used. Thermally insulate samples that are potentially sensitive to changes in temperature.
    d. *Soil-Like care* – handle per ASTM Standard D 4220.
12. Drilling conditions and sequence (fluid loss, circulation pressures, depths of lost circulation, down feed pressures, core blockage etc.) should be documented on the boring log as described in SOP 10.3.
13. Drill cuttings and fluids should be appropriately controlled and contained as investigation-derived material per SOP 70.1.
14. The drill rod assembly, sampling devices, and other drilling equipment contacting potentially contaminated material must be decontaminated before and after each use per the methods specified in SOP 80.1.
15. Borehole logging should be completed per SOP 10.3.
16. Borehole abandonment, when required, should be conducted according to SOP 20.3.

4.0 MAINTENANCE

Not applicable.

5.0 PRECAUTIONS

Refer to site-specific health and safety plan included in work plan addenda.

STANDARD OPERATING PROCEDURE 30.1
SOIL SAMPLING

1.0 SCOPE AND APPLICATION

The purpose of this standard operating procedure (SOP) is to delineate protocols for sampling surface and subsurface soils.

2.0 MATERIALS

- Stainless steel scoop, spoon, trowel, knife, spatula, (as needed);
- Split-spoon, Shelby tube, or core barrel sampler;
- Hand auger or push tube sampler;
- Drill rig and associated equipment (subsurface soil);
- Stainless steel bowls;
- Photoionization detector or other appropriate instrument as specified in site-specific health and safety plan;
- Sampling equipment for collection of volatile organic samples;
- Appropriate sample containers;
- Appropriate sample labels and packaging material.;
- Personal protective equipment and clothing (PPE) per site-specific health and safety plan; and
- Decontamination equipment and supplies (SOP 80.1).

3.0 PROCEDURE

3.1 DOCUMENTATION

Soil sampling information should be recorded in the field logbooks as described in SOPs 10.1 and 10.2.

3.2 SURFICIAL SOIL SAMPLES

The targeted depths for surficial soil samples (surface and near surface) will be specified in the work plan addenda developed for site-specific investigations.

1. All monitoring equipment should be appropriately calibrated before beginning sampling according to the requirements of the work plan addenda and SOP 90.1 or 90.2.
2. All sampling equipment should be appropriately decontaminated before and after use according to the requirements of the work plan addendum and SOP 80.1.
3. Use a spade, shovel, or trowel or other equipment (manufactured from material, which is compatible with the soil to be sampled) to remove any overburden material present (including vegetative mat) to the level specified for sampling.
4. Measure and record the depth at which the sample will be collected with an engineers scale or tape.

5. Remove the thin layer that was in contact with the overburden removal equipment using a clean stainless steel scoop or equivalent and discard it.
6. Begin sampling with the acquisition of any discrete sample(s) for analysis of volatile organic compounds (VOCs), with as little disturbance as possible. VOC samples will not be composited or homogenized.
7. When a sample will not be collected with a core type of sampler (push tube, split spoon, etc.), the sample for VOC analysis will be collected from freshly exposed soil. The method of collection will follow the procedures specified in SOP 30.8 (Methanol Preservation Method) or 30.9 (En Core® Method) based on the requirements of the work plan addenda.
8. Field screen the sample with properly calibrated photoionization detector (PID) or other appropriate instrument. Cut a cross-sectional slice from the core or center of the sample and insert the monitoring instrument(s). Based on the screening results, collect the VOC fraction, as applicable.
9. Collect a suitable volume of sample from the targeted depth with a clean stainless steel scoop (or similar equipment), push tube sampler, or bucket auger
10. For core type of samplers, rough trimming of the sampling location surface should be considered if the sampling surface is not fresh or other waste, different soil strata, or vegetation may contaminate it. Surface layers can be removed using a clean stainless steel, spatula, scoop, or knife. Samples collected with a bucket auger or core type of sampler should be logged per the requirements of SOP 10.3.
11. If homogenization or compositing of the sampling location is not appropriate for the remaining parameters, the sample should be directly placed into appropriate sample containers with a stainless steel spoon or equivalent.
12. If homogenization of the sample location is appropriate or compositing of different locations is desired, transfer the sample to a stainless steel bowl for mixing. The sample should be thoroughly mixed with a clean stainless steel spoon, scoop, trowel, or spatula and then placed in appropriate sample containers per the requirements for containers and preservation specified in work plan addenda. Secure the cap of each container tightly.
13. Appropriately, label the samples (SOP 50.1), complete the chain-of-custody (SOP 10.4), and package the samples for shipping (SOP 50.2).
14. Return any remaining unused soil to the original sample location. If necessary, add clean sand to bring the subsampling areas back to original grade. Replace the vegetative mat over the disturbed areas.

3.3 SUBSURFACE SAMPLES

All sampling equipment should be appropriately decontaminated before and after use according to the requirements of the work plan addendum and SOP 80.1.

1. All monitoring equipment should be appropriately calibrated before sampling according to the requirement of the work plan addendum and SOP 90.1 or SOP 90.2.
2. All sampling equipment should be appropriately decontaminated before and after use according to the requirements of the work plan addendum and SOP 80.1.
3. Collect split-spoon; core barrel, Shelby tube, sonic core or other similar samples during drilling.
4. Upon opening sampler or extruding sample, immediately screen soil for VOCs using a PID or appropriate instrument. If sampling for VOCs, determine the area of highest concentration; use a

stainless steel knife, trowel, or lab spatula to cut the sample; and screen for VOCs with monitoring instrument(s).

5. Log the sample on the boring log before extracting from the sampler per the requirements of SOP 10.3.
6. Any required VOC samples will be collected first followed by the other parameters. VOC samples will not be composited or homogenized and will be collected from the area exhibiting the highest screening level. The method of VOC sample collection will follow the procedures specified in SOP 30.8 (Methanol Preservation Method) or 30.9 (En Core® Method) based on the requirements of the work plan addenda.
7. Field screen the sample with properly calibrated photoionization detector (PID) or other appropriate instrument. Cut a cross-sectional slice from the core or center of the sample and insert the monitoring instrument(s). Based on the screening results, collect the VOC fraction, as applicable.
8. Rough trimming of the sampling location surface should be considered if the sampling surface is not fresh or other waste, different soil strata, or vegetation may contaminate it. Surface layers can be removed using a clean stainless steel, spatula, scoop, or knife.
9. If homogenization or compositing of the sampling location is not appropriate for other parameters, the sample should be directly placed into appropriate sample containers with a stainless steel spoon or equivalent.
10. If homogenization of the sample location is appropriate or compositing of different locations is desired, transfer the sample to a stainless steel bowl for mixing. The sample should be thoroughly mixed with a clean stainless steel spoon, scoop, trowel, or spatula and placed in appropriate sample containers per the requirements for containers and preservation specified in work plan addenda. Secure the cap of each container tightly.
15. Appropriately, label the samples (SOP 50.1), complete the chain-of-custody (SOP 10.4), and package the samples for shipping (SOP 50.2).
16. Discard any remaining sample into the drums used for collection of cuttings.
17. Abandon borings according to procedures outlined in SOP 20.2.

3.4 INVESTIGATION-DERIVED MATERIAL

Investigation-derived material will be managed in accordance with procedures defined in the work plan addenda for the site being investigated and SOP 70.1.

NOTES: If sample recoveries are poor, it may be necessary to composite samples before placing them in jars. In this case, the procedure will be the same except that two split-spoon samples (or other types of samples) will be mixed together. The boring log should clearly state that the samples have been composited, which samples were composited, and why the compositing was done. In addition, VOC fraction should be collected from the first sampling device.

When specified, samples taken for geotechnical analysis (e.g., percent moisture, density, porosity, and grain size) will be undisturbed samples, such as those collected using a thin-walled (Shelby tube) sampler, sonic core sampler, etc.

4.0 MAINTENANCE

Not applicable.

5.0 PRECAUTIONS

Refer to the site-specific health and safety plan.

Soil samples will not include vegetative matter, rocks, or pebbles unless the latter are part of the overall soil matrix.

STANDARD OPERATING PROCEDURE 30.2
GROUNDWATER SAMPLING

1.0 SCOPE AND APPLICATION

The purpose of this standard operating procedure (SOP) is to delineate protocols for the collection of groundwater samples from monitoring wells.

2.0 MATERIALS

- Work Plans;
- Field logbooks and field parameter forms;
- Plastic sheeting;
- Decontamination equipment and supplies (SOP 80.1);
- Variable-speed, low-flow submersible pump with safety drop cable;
- Nylon stay-ties;
- Generator;
- Dedicated Teflon tubing or Teflon lined polyethylene tubing;
- Flow-through-cell and probes for measuring pH, temperature, specific conductance, oxidation/reduction potential, dissolved oxygen, and turbidity (SOP 40.1);
- Electronic water-level indicator;
- Appropriate sample bottles, labels, chain-of-custody forms, and sample shipping supplies etc;
- Cooler with ice;
- Silicone tubing;
- 0.45-micron disposable filters (as appropriate).
- Personal protective equipment and clothing (PPE) per site-specific health and safety plan;
- Photoionization detector (PID) or other appropriate monitoring instrument per the site-specific health and safety plan; and
- Appropriate containers for investigation-derived material.

3.0 PROCEDURE

3.1 DOCUMENTATION

Groundwater sampling information should be recorded in the field logbooks as described in SOPs 10.1 and 10.2.

The following are general rules for the field parameter logbook for groundwater, as described in SOP 10.2:

- Only information for one site or installation per logbook. The same book maybe used for more than one sampling event.

- The first five pages will be reserved for index, general notes, etc. Sign and date each entry.
- Fill in the forms.
- Duplicate copies, index pages, and calibration sheets remain intact.

3.2 OVERVIEW OF SAMPLING TECHNIQUES

In general, two different techniques may be used to sample groundwater from monitoring wells at Radford Army Ammunition Plant (RFAAP):

- Low flow purging and sampling (Type I); and
- Conventional purging and low-flow sampling (Type II).

These two sampling techniques are intended to address the different groundwater conditions that may be encountered at RFAAP.

The Type I sampling technique will be used in the following situations:

- In wells where only one discrete water-producing zone is encountered;
- In wells with no discrete water bearing zone and a low yield (generally < 0.5 liters per minute); and
- In wells sampled during seasonal low groundwater conditions with greatly reduced yield.

The Type II sampling technique will be used in the following situations:

- In a well with potential or documented multiple flow zones and where individual flow zones will not be evaluated;
- In moderately producing wells (>0.5 liters per minute) where no discrete flow zones were documented during drilling; and
- In wells sampled during seasonal high groundwater conditions with enhanced yield (and potentially additional flow zones).

Groundwater samples should be collected no sooner than 14 days after well development. Information from the boring logs, well completion records, and well development records should be reviewed before sampling a well to determine the most appropriate sampling technique. Pertinent information for each well to be sampled includes:

- Well construction;
- Depth and nature of water producing zones;
- Sustainable pumping rate of the well to be sampled;
- Well recharge characteristics; and
- Baseline turbidity.

Because of the heterogeneous nature of the fracture and solution-enhanced fractured bedrock at RFAAP, monitoring well purging and sampling techniques will need to be flexible. This flexibility is necessary to obtain representative samples that meet the data quality objectives (DQOs) specified in site-specific work plan addenda.

In general, when using the pumps specified in the following sections, situate any gasoline-powered generator on level ground approximately 15 ft downwind from the well. All generator maintenance (oil and fueling) is to be performed off site. If the hose(s) and/or power cord of the pump is not on a reel, place the pump with its hose and power cord on the plastic sheeting downhill from the well.

3.3 TYPE I SAMPLING PROCEDURES

Type I low flow purging and sampling procedures include the following:

- The work area outside the well will be prepared by placing plastic sheeting on the ground around the well casing to avoid cross-contamination.
- All equipment used to purge and sample the wells will be thoroughly decontaminated before and after use according to the requirements of the work plan addenda and SOP 80.1.
- All equipment to be used for monitoring water quality parameters will be calibrated before beginning purging according to the requirements of the work plan addenda and SOP 40.1.
- Note the condition of the well and well head.
- Monitor the headspace of the well with a photoionization detector as the well cap is removed.
- Measure and record the depth to water with an electronic water level indicator. The measurement of well depth will not be taken until after sampling is completed so that potential re-suspension of any settled solids at the bottom of the well is avoided.
- Well depth at the time of purging will be obtained from well construction and existing data.
- Slowly lower a clean, stainless steel, adjustable flow rate, submersible pump and dedicated Teflon or Teflon-lined polyethylene tubing to the desired depth. As the pump is slowly lowered into the well, secure the safety drop cable, tubing, and electrical lines to each other using nylon stay-ties.
- For wells with very low sustainable pumping rates (≤ 0.5 liters per minute), the pump should be set in the middle of the saturated screen section of the well or middle of the water column for open wells. The pump should be set 12 hours prior to purging so that the depth to water equilibrates and sediments disturbed during pump placement have time to settle.
- For wells with sustainable pumping rates (> 0.5 liters per minute), the pumps will be set at a desired depth prior to purging, allowing for the depth to water to equilibrate before sampling. The desired depth will be specified in work plan addenda based on site-specific conditions and DQOs.
- Connect the pump tubing to an in-line flow-through cell(s) and connect the multi-parameter probe to the cell(s). The end of the tubing exiting the in-line flow-through cell should be placed to discharge into a appropriate container(s) to collect purge water.
- Immediately prior to purging, the depth to water will be measured and record. Start pumping the water at a rate of 100 to 400 milliliters per minute. Avoid surging. The pumping rate should cause minimal drawdown (less than 0.2 ft). Water level measurements should be collected continuously to document stabilization of the water level. Pumping rates should, if needed, be reduced to the minimal capabilities of the pump to avoid dewatering the screen interval and ensure stabilization of indicator parameters.
- During purging, water quality indicator parameters will be monitored at the in-line flow-through cell(s) every 3 to 5 minutes. The parameters to be monitored include pH, specific conductance, oxidation/reduction potential (Eh), dissolved oxygen, and turbidity.
- Continue purging until stabilization of indicator parameters is achieved. Stabilization is defined as three consecutive readings that are within the following criteria:
  - ± 0.1 for pH;
  - ±3% for specific conductance;
  - ±10 mV for oxidation/reduction potential (Eh); and

- ±10% for turbidity and dissolved oxygen.

- If the parameters have stabilized, but the turbidity is not in the range of 5 to 10 NTU, then both filtered and unfiltered samples should be collected for any metals analysis. Filter metal samples should be collected with an in-line filter using a high capacity 0.45-micron particulate filter. This filter should be pre-rinsed according to the manufacturer's instructions.
- Once purging is completed, reduce the pumping rate to its lowest steady rate and disconnect the tubing from the in-line flow-though cell(s).
- Collect groundwater samples directly from the end of the tubing into clean containers provided by the laboratory. The container requirements and preservatives for groundwater samples are specified in work plan addenda. Allowing the pump discharge to flow gently down the inside of the container with minimal turbulence should fill all sample containers. Volatile organic compound (VOC) and gas sensitive parameter samples should be collected first followed by other parameters.
- In general, samples should be collected and containerized in the order of the volatilization sensitivity of the parameters. A preferred collection order for some common parameters is VOCs, extractable organics, metals, cyanide, sulfate and chloride, turbidity, and nitrate and ammonia. The parameters to be collected at any well location are site-specific and are specified in work plan addenda.
- Appropriately, label the samples (SOP 50.1), complete the chain-of-custody (SOP 10.4), and package the samples for shipping (SOP 50.2).
- After the sample collection is complete; remove the pump, tubing, and associated lines. Note: sample tubing will be dedicated to each well.
- Measure and record the total depth of the well.
- Secure the well be replacing and locking the lid.

3.4 TYPE II SAMPLING PROCEDURES

- The work area outside the well will be prepared by placing plastic sheeting on the ground around the well casing to avoid cross-contamination.
- All equipment used to purge and sample the wells will be thoroughly decontaminated before and after use according to the requirements of the work plan addenda and SOP 80.1.
- All equipment to be used for monitoring water quality parameters will be calibrated before beginning purging according to the requirements of the work plan addenda and SOP 40.1.
- Note the condition of the well and well head.
- Monitor the headspace of the well with a photoionization detector as the well cap is removed.
- Measure and record the depth to water with an electronic water level indicator. The measurement of well depth will not be taken until after sampling is completed so that potential re-suspension of any settled solids at the bottom of the well is avoided.
- Well depth at the time of purging will be obtained from well construction and existing data.
- Calculate the standing water column in the well by subtracting the depth to water from the total depth of the well as recorded during completion of the well.
- From the water depth, well diameter, sand pack length, etc., calculate the equivalent volume (1 EV) of water in the well.

1 EV = volume in casing + volume in saturated sand pack. Therefore; if the water table lies below the top of the sand pack, use the following equation:

$1\ EV = (pR_w^2h_w) + (0.30p(R_s^2-R_w^2)h_w) * (0.0043)$

If the water table lies above the top of the sand pack use this equation:

$1\ EV = [(pR_w^2h_w) + (0.30p(R_s^2-R_w^2)h_s)] * (0.0043)$

Where: R_s = radius of sand pack in inches
R_w = radius of well casing in inches
h_s = height of sand pack in inches
h_w = water depth in inches

$0.0043\ gal/in^3$
Assumed filter pack porosity = 30%

Tables and graphs showing equivalent volumes for typical well constructions are available.

- Slowly lower a clean, stainless steel, adjustable flow rate, submersible pump and dedicated Teflon or Teflon-lined polyethylene tubing to the middle of the saturated screen interval or water column in an open borehole. As the pump is slowly lowered into the well, secure the safety drop cable, tubing, and electrical lines to each other using nylon stay-ties.
- Connect the pump tubing to an in-line flow-through cell(s) and connect the multi-parameter probe to the cell(s). The end of the tubing exiting the in-line flow-through cell should be placed to discharge into an appropriate container to collect purge water.
- Start purging the well at the minimally achievable pumping rate. Gradually increase the pumping rate to achieve the maximum flow rate of the pump or the maximum sustainable flow rate that does not draw down the static water level to a point below the top of the first water bearing zone, whichever is achieved first.
- During purging, water level measurements should be collected periodically to verify water levels in the well.
- During purging, water quality indicator parameters will be monitored at the in-line flow-through cell(s) every 3 to 5 minutes. The parameters to be monitored include pH, specific conductance, oxidation/reduction potential (Eh), dissolved oxygen, and turbidity.
- Note when each indicator parameter stabilizes. Stabilization is defined as three consecutive readings that are within the following criteria:
  - ± 0.1 for pH;
  - ±3% for specific conductance;
  - ±10 mV for oxidation/reduction potential (Eh); and
  - ±10% for turbidity and dissolved oxygen.
- Three calculated eVs of water in the will be purged prior to sampling. It will be documented if stabilization of the indicator parameters has not occurred after three calculated well volumes have been removed and sampling procedures begin.
- If the turbidity is not in the range of 5 to 10 NTU when purging has been completed, then both filtered and unfiltered samples should be collected for any metals analysis. Filter metal samples should be collected with an in-line filter using a high capacity 0.45-micron particulate filter. This filter should be pre-rinsed according to the manufacturer's instructions.

- Once purging is completed, reduce the pumping rate to its lowest steady rate and disconnect the tubing from the in-line flow-though cell(s).
- Collect groundwater samples directly from the end of the tubing into clean containers provided by the laboratory. The container requirements and preservatives for groundwater samples are specified in work plan addenda. Allowing the pump discharge to flow gently down the inside of the container with minimal turbulence should fill all sample containers. Volatile organic compound (VOC) and gas sensitive parameter samples should be collected first followed by other parameters.
- Appropriately, label the samples (SOP 50.1), complete the chain-of-custody (SOP 10.4), and package the samples for shipping (SOP 50.2).
- After the sample collection is complete; remove the pump, tubing, and associated lines. Note: sample tubing will be dedicated to each well.
- Measure and record the total depth of the well.
- Secure the well be replacing and locking the lid.

3.5 INVESTIGATION-DERIVED MATERIAL

Investigation-derived material will be managed in accordance with procedures defined in the work plan addendum for the site being investigated and SOP 70.1.

4.0 MAINTENANCE

Refer to manufacturer's requirements for maintenance of pumps and generators.

5.0 PRECAUTIONS

Refer to the site-specific health and safety plan.

STANDARD OPERATING PROCEDURE 30.7
SAMPLING STRATEGIES

1.0 SCOPE AND APPLICATION

The purpose of this standard operating procedure (SOP) is to delineate sampling strategies for sampling various media.

2.0 MATERIALS

- Historical site data;
- Site topography;
- Soil types; and
- Sampled media.

3.0 PROCEDURE

The primary goal of any investigation is to collect samples representative of existing site conditions. Statistics are generally used to ensure samples are as representative as possible. Sampling plans may employ more than one approach to ensure project data quality objectives are adequately addressed. A comparison of sampling strategies is presented in Table 1.

3.1 CLASSICAL STATISTICAL SAMPLING

Classical statistical sampling strategies are appropriately applied to either sites where the source of contamination is known or small sites where the entire area is remediated as one unit. Primary limitations of this sampling approach include (1) inability to address media variability; (2) inadequate characterization of heterogenous sites; and (3) inadequate characterization of sites with unknown contamination characteristics.

3.1.1 Simple Random Sampling

Simple random sampling is generally more costly than other approaches because of the number of samples required for site characterization. This approach is generally used when minimal site information is available and visible signs of contamination are not evident and includes the following features:

- Sampling locations are chosen using random chance probabilities.
- This strategy is most effective when the number of sampling points is large.

3.1.2 Stratified Random Sampling

This sampling approach is a modification to simple random sampling. This approach is suited for large site investigations that encompass a variety of soil types, topographic features, and/or land uses. By dividing the site into homogenous sampling strata based on background and historical data, individual random sampling techniques are applied across the site. Data acquired from each stratum can be used to determine the mean or total contaminant levels and provide these advantages:

- Increased sampling precision results due to sample point grouping and application of random sampling approach.
- Control of variances associated with contamination, location, and topography.

3.1.3 Systematic Grid

The most common statistical sampling strategy is termed either systematic grid or systematic random sampling. This approach is used when a large site must be sampled to characterize the nature and extent of contamination.

Samples are collected at predetermined intervals within a grid pattern according to the following approach:

- Select the first sampling point randomly; remaining sampling points are positioned systematically from the first point.
- Determine the grid design: one or two-dimensional. One-dimensional sample grids may be used for sampling along simple man-made features. Two-dimensional grid systems are ideal for most soil applications.
- Determine the grid type: square or triangular. Sampling is usually performed at each grid-line intersection. Other strategies include sampling within a grid center or obtaining composite samples within a grid.
- Each stratum is sampled based on using the simple random sampling approach but determined using a systematic approach.

3.1.4 Hot-Spot Sampling

Hot spots are small, localized areas of media characterized by high contaminant concentrations. Hot-spot detection is generally performed using a statistical sampling grid. The following factors should be addressed:

- Grid spacing and geometry. The efficiency of hot-spot searches is improved by using a triangular grid. An inverse relationship exists between detection and grid point spacing, e.g., the probability of hot-spot detection is increased as the spacing between grid points is decreased.
- Hot-spot shape/size. The larger the hot spot, the higher the probability of detection. Narrow or semi-circular patterns located between grid sampling locations may not be detected.
- False-negative probability. Estimate the false negative (β-error) associated with hot-spot analysis.

3.1.5 Geostatistical Approach

Geostatistics describe regional variability in sampling and analysis by identifying ranges of correlation or zones of influence. The general two-stage approach includes the following:

- Conducting a sampling survey to collect data defining representative sampling areas.
- Defining the shape, size, and orientation of the systematic grid used in the final sampling event.

3.2 NON-STATISTICAL SAMPLING

3.2.1 Biased Sampling

Specific, known sources of site contamination may be evaluated using biased sampling. Locations are chosen based on existing information.

3.2.2 Judgmental Sampling

This sampling approach entails the subjective selection of sampling locations that appear to be representative of average conditions. Because this method is highly biased, it is suggested that a measure of precision be included through the collection of multiple samples.

4.0 MAINTENANCE

Not applicable.

TABLE 1
SAMPLING STRATEGIES

SAMPLING STRATEGY	DESCRIPTION	APPLICATION	LIMITATIONS
Classical Statistical Sampling Strategies			
Simple Random Sampling	Representative sampling locations are chosen using the theory of random chance probabilities.	Sites where background information is not available and no visible signs of contamination are present.	May not be cost-effective because samples may be located too close together. Does not take into account spatial variability of media.
Stratified Random Sampling	Site is divided into several sampling areas (strata) based on background or site survey information.	Large sites characterized by a number of soil types, topographic features, past/present uses, or manufacturing storage areas.	Often more cost-effective than random sampling. More difficult to implement in the field and analyze results. Does not take into account spatial variability of media.
Systematic Grid Sampling	Most common statistical strategy; involves collecting samples at predetermined, regular intervals within a grid pattern.	Best strategy for minimizing bias and providing complete site coverage. Can be used effectively at sites where no background information exists. Ensures that samples will not be taken too close together.	Does not take into account spatial variability of media.
Hot-Spot Sampling	Systematic grid sampling strategy tailored to search for hot spots.	Sites where background information or site survey data indicate that hot spots may exist.	Does not take into account spatial variability of media. Tradeoffs between number of samples, chance of missing a hot spot, and hot spot size/shape must be weighed carefully.
Geostatistical Approach	Representative sampling locations are chosen based on spatial variability of media. Resulting data are analyzed using kriging, which creates contour maps of the contaminant concentrations and the precision of concentration estimates.	More appropriate than other statistical sampling strategies because it takes into account spatial variability of media. Especially applicable to sites where presence of contamination is unknown.	Previous investigation data must be available and such data must be shown to have a spatial relationship.
Non-Statistical Sampling Strategies			
Biased Sampling	Sampling locations are chosen based on available information.	Sites with known contamination sources.	Contaminated areas can be overlooked if background information or visual signs of contamination do not indicate them. Best used if combined with a statistical approach, depending on the project objectives.
Judgmental Sampling	An individual subjectively selects sampling locations that appear to be representative of average conditions.	Homogenous, well-defined sites.	Not usually recommended due to bias imposed by individual, especially for final investigations.

STANDARD OPERATING PROCEDURE 30.9
COLLECTION OF SOIL SAMPLES BY USEPA SW 846 METHOD 5035 USING DISPOSABLE SAMPLERS

1.0 SCOPE AND APPLICATION

This standard operating procedure (SOP) outlines the recommended protocol and equipment for collection of representative soil samples to monitor potential volatile organic contamination in soil samples.

This method of sampling is appropriate for surface or subsurface soils contaminated with low to high levels of volatile organic compounds (VOCs). This sampling procedure may be used in conjunction with any appropriate determinative gas chromatographic procedure, including, but not necessarily limited to, SW-846 Method 8015, 8021, and 8260.

2.0 MATERIALS

- Work Plans;
- Field Logbook;
- Photoionization Detector (PID) or other monitoring instrument(s) per site-specific health and safety plan;
- Personal protective equipment and clothing per site-specific health and safety plan;
- Soil sampling equipment, as applicable (SOP 30.1);
- Disposable sampler;
- T-handle and/or Extrusion Tool; and
- Decontamination equipment and supplies (SOP 80.1).

3.0 PROCEDURE

3.1 METHOD SUMMARY

Disposable samplers are sent to the field to be used to collect soil samples. Three samplers must be filled for each soil sampling location, two for the low-level method (sodium bisulfate preservation) and one for the high level method (methanol preservation). After sample collection, disposable samplers are immediately shipped back to the laboratory for preservation (adding soil sample into methanol and sodium bisulfate solution). The ratio of volume of methanol to weight of soil is 1:1 as specified in SW-846 Method 5035 (Section 2.2.2). The amount of preservative in the solution corresponds to approximately 0.2 g of preservative for each 1 g of sample. Enough sodium bisulfate should be present to ensure a sample pH of ≤ 2.

If quality assurance/quality control (QA/QC) samples are needed, seven samplers will be needed for the original, matrix spike, and matrix spike duplicate analysis. Soil samples are collected in the field using the disposable samplers, sealed and returned to the laboratory. A separate aliquot of soil is collected in a 125-mL container for dry weight determination.

3.2 SAMPLE CONTAINERS, PRESERVATION, HANDLING AND STORAGE

After sample collection, the disposable samplers must be cooled to and maintained at 4°C. The contents of the samplers will be analyzed using EPA methods 8015, 8021, and/or 8260. The **disposable** sampler is a single use device. It cannot be cleaned and/or reused.

Disposable samplers have a 48 hour holding time from sample collection to sample preparation in the laboratory. Return the samplers to the laboratory immediately after sampling.

3.3 SAMPLE PROCEDURES

Before sampling, the disposable sampler should be prepared as follows:

1. Unpack the cooler/sampling kit received from the laboratory. Disposable samplers are packed in sealed aluminized bags. These should be over packed in plastic zip lock bags. A T-Handle will also be needed to collect samples with the disposable sampler.
2. Hold coring body and push plunger rod down until small 0-ring rests against tabs. This will assure that plunger moves freely.
3. Depress locking lever on the sampler T-Handle (or other extraction device). Place coring body, plungers end first, into the open end of the T-Handle, aligning the two slots on the coring body with the two locking pins in the T-Handle. Twist the coring body clockwise to lock the pins in the slots. Check to ensure the sampler is locked in place. Sampler is ready for use.

The following procedure should be followed when using a disposable sampler to sample for VOCs in soil:

1. After the soil-sampling device (split spoon, corer, etc.) is opened, the sampling process should be completed in a minimum amount of time with the least amount of disruption.
2. Visual inspection and soil screening should be conducted after the sampler is opened and a fresh surface is exposed to the atmosphere. Soil screening should be conducted with an appropriate instrument (PID or FID).
3. Rough trimming of the sampling location surface should be considered if the sampling surface is not fresh or other waste, different soil strata, or vegetation may contaminate it. Surface layers can be removed using a clean stainless steel, spatula, scoop, or knife.
4. Orient the T-Handle with the T-up and the coring body down. This positions the plunger bottom flush with bottom of coring body (ensure that plunger bottom is in position). Using T-Handle, push sampler into soil until the coring body is completely full taking care not to trap air behind the sampler. When full, the small o-ring will be centered in the T-Handle viewing hole. Remove sampler from soil. Wipe excess soil from coring body exterior with a clean disposable paper towel.
5. Cap coring body while it is still on the T-Handle. ***Push*** cap over flat area of ridge ***and twist*** to lock cap in place. ***Cap must be seated to seal sampler.***
6. Remove the capped sampler by depressing locking lever on T-Handle while twisting and pulling sampler from T-Handle.
7. Lock plunger by rotating extended plunger rod fully counterclockwise until wings rest firmly against tabs.
8. Fill the 125-mL wide mouth jar for the non-preserved portion of the sample to be used for a moisture determination. These may be in a cardboard box. Retain all packaging to return the samples.
9. The disposable sampler should collect approximately 5 grams of soil (not necessary to weigh in the field). After a sample has been collected and capped, tear off the identification tag found at the bottom of the label on the aluminized bag. This tag is added to the sampler on the cap used to seal the sampler.

10. Place the sampler back in the aluminized bag and seal the top (a zip-lock seal). Make sure all the appropriate information is on the label. Record the sampler ID number on the chain-of-custody. Make sure each sampler and 125-mL container is labeled with the same location identification. The sampler should be placed inside the plastic zip-lock bags.

11. Place the 125-mL wide mouth jars in the cooler with the sampler on top. These should be sandwiched between bags of ice to maintain the correct temperature. If sent with the jars and samplers, a temperature bottle (used to evaluate the temperature on receipt) should be placed in the middle of the jars. The sample temperature should be 4ºC during shipment.

12. Ship the samples so that they will be received within 24 hours of sampling. The laboratory must receive the sampler within 40 hours of the collection so that they can be correctly preserved.

3.4 QUALITY ASSURANCE/QUALITY CONTROL (QA/QC)

1. All data must be documented on chain-of-custody forms, field data sheets and in the field logbook.

2. An equipment blank is a QA/QC sample that will determine potential contamination from sampling equipment used to collect and transfer samples from the point of collection to the sample container. An equipment blank is performed by pouring demonstrated analyte free water from one sample container, over a sampler, and into a separate set of identical sample containers. The equipment blank is optional when sampling with the methanol preservation technique. It may be required on a site-specific basis if elevated analytical results are suspected to be due to cross contamination from sampling equipment.

3. A trip blank is a QA/QC sample, which will determine additional sources of contamination that may potentially influence the samples. The sources of the contamination may be from the laboratory, sample containers, or during shipment. The laboratory prepares a trip blank at the same time and in the same manner as the sample containers. The trip blank must accompany the sample containers to the field and back to the laboratory along with the collected samples for analysis. It must remain sealed at all times until it is analyzed at the laboratory. The frequency of collection for the trip blank must be at a rate of one per sample shipment.

3.5 LIMITATIONS IN SAMPLING

This sampling protocol will not be applicable to all solid environmental matrices, such as those that cannot be cored including non-cohesive granular material, gravel, or hard dry clay. In this case, the procedure for collecting VOC samples using Methanol Preservation should be used (see SOP 30.8).

4.0 MAINTENANCE

Not applicable.

5.0 PRECAUTIONS

None.

STANDARD OPERATING PROCEDURE 40.1
MULTIPARAMETER WATER QUALITY MONITORING INSTRUMENT

1.0 SCOPE AND APPLICATION

The purpose of this standard operating procedure (SOP) is to delineate protocols for field operation with the multiparameter water quality logging system (data transmitter and visual display). This system can monitor up to eleven basic parameters, including dissolved oxygen, percent saturation, temperature, pH, specific conductance, resistivity, salinity, total dissolved solids, redox, level, and depth.

2.0 MATERIALS

- Visual display;
- Data transmitter;
- Underwater cables; and
- Field logbooks.

3.0 PROCEDURE

3.1 CALIBRATION

Calibration will be performed in the field daily before use according to manufacturer's specifications. The following parameters are calibrated to the following standards:

- Temperature—none required;
- Specific conductance—KCl or seawater standards;
- pH—pH 7 buffer plus a slope buffer;
- Dissolved oxygen—saturated air or saturated water;
- Redox—quinhydrone or transfer;
- Depth—set zero in air;
- Level—set zero in air; and
- Salinity—uses calibration for specific conductance.

3.2 OPERATION

1. Attach the cable to the transmitter.
2. Connect the other end of the cable to the display.
3. Press the On/Off key on the display panel. Allow a few seconds for the transmitter to start sending data to the display screen.
4. Calibrate the transmitter.
5. Deploy the sensor into a minimum of 4 in. of water.
6. Write data values from the display screen in the appropriate field logbook.

7. Retrieve sensor and clean the transmitter to prevent cross-contamination.
8. Move to the next sampling location. If travel time is great, turn off display by pressing On/Off key. Check condition of probes after each deployment.
9. Disconnect the transmitter when finished sampling for the day.

4.0 MAINTENANCE

Maintain according to specific manufacturer's specifications.

5.0 PRECAUTIONS

- Check condition of probes frequently between sampling; and
- Do not force pins into the connectors; note the keying sequence.

6.0 REFERENCES

Manufacturer's Handbook.

STANDARD OPERATING PROCEDURE 40.2
WATER LEVEL AND WELL-DEPTH MEASUREMENTS

1.0 SCOPE AND APPLICATION

The purpose of this standard operating procedure (SOP) is to delineate protocols for measuring water level and well depth. This procedure is applicable to the sampling of monitoring wells and must be performed before any activities that may disturb the water level, such as purging or aquifer testing.

2.0 MATERIALS

- Work Plans;
- Well construction diagrams;
- Field logbook;
- Photoionization detector (PID) or other monitoring instruments per site-specific health and safety plan;
- Decontamination equipment and supplies (SOP 80.1);
- Electric water level indicator (dipmeter) with cable measured at 0.01 ft increments;
- Oil-water interface probe (if non-aqueous phase liquid (NAPLs) are suspected to be present); and
- Plastic sheeting.

3.0 PROCEDURE

3.1 PRELIMINARY STEPS

1. Locate the well and verify its position on the site map. Record whether positive identification was obtained, including the well number and any identifying marks or codes contained on the well casing or protective casing. Gain access to the top of the well casing.
2. Locate the permanent reference mark at the top of the casing. This reference point will be scribed, notched, or otherwise noted on the top of the casing. If no such marks are present, measure to the top of the highest point of the well casing and so note this fact in field logbook. Determine from the records and record in the notebook the elevation of this point.
3. Record any observations and remarks regarding the completion characteristics and well condition, such as evidence of cracked casing or surface seals, security of the well (locked cap), and evidence of tampering.
4. Keep all equipment and supplies protected from gross contamination; use clean plastic sheeting. Keep the water level indicator probe in its protective case when not in use.

3.2 OPERATION

1. Sample the air in the well head for gross organic vapors by lifting the well cap only high enough for an organic vapor meter (PID or FID) probe to be entered into the well casing. This will indicate the presence of gross volatile contaminants as well as indicating potential sampler exposure.

2. Remove cap. Allow well to vent for 60–90 seconds. Resample headspace. Record both readings. If the second reading is lower than the first, use the second reading to determining whether respiratory protection will be required during subsequent water level and well depth determinations and sampling.
3. Note that all headspace sampling must be performed at arm's length and from the upwind side of the well if possible.
4. If NAPL contamination is suspected, use an interface probe to determine the existence and thickness of NAPLs.
    - Open the probe housing, turn the probe on, and test the alarm. Slowly lower the probe into the well until the alarm sounds. A continuous alarm indicates a NAPL, while an intermittent alarm indicates water. If a NAPL is detected, record the initial level (first alarm). Mark the spot by grasping the cable with the thumb and forefingers at the top of the casing. If a mark is present on the casing, use the mark as the reference point. If no mark is present, use the highest point on the casing as the reference point. Withdraw the cable sufficiently to record the depth.
    - Continue to slowly lower the probe until it passes into the water phase. Slowly retract the probe until the NAPL alarm sounds and record that level in the manner as described above.
    - Record the thickness of the LNAPL (see Section 3.3.1).
    - Continue to slowly lower the interface probe through the water column to check for the presence of DNAPL.
    - Measure and record the thickness of the DNAPL layer (if any) as described above.
    - Slowly raise the interface probe, recording the depth to each interface as the probe is withdrawn. If there is a discrepancy in depths, clean the probe sensors and re-check the depths.
    - NOTE: Air-liquid interface depth is more reliable if probe is lowered into liquid. NAPL-water depths are more accurate if probe is moved from water into NAPL.
    - Always lower and raise interface probe slowly to prevent undue mixing of media.
    - Always perform NAPL check in wells installed in areas with suspected NAPL contamination. Always perform NAPL check if headspace test reveals presence of volatiles. Always perform NAPL check the first time a well is sampled. If a well has been sampled previously and no NAPLs were present and none of the proceeding conditions are met, the NAPL check may be omitted.
5. If no NAPL is present, use an electronic water level detector as follows.
    - Remove the water level indicator probe from the case, turn on the sounder, and test check the battery and sensitivity scale by pushing the red button. Adjust the sensitivity scale until you can hear the buzzer.
    - Slowly lower the probe and cable into the well, allowing the cable reel to unwind. Continue lowering until the meter buzzes. Very slowly, raise and lower the probe until the point is reached where the meter just buzzes. Marking the spot by grasping the cable with the thumb and forefingers at the top of the casing. If a mark is present on the casing, use the mark as the reference point. If no mark is present, use the highest point on the casing as the reference point. Withdraw the cable and record the depth.
6. To measure the well depth, lower electric water level indicator probe or tape until slack is noted. Very slowly raise and lower the cable until the exact bottom of the well is “felt.” Measure (cable) or read the length (tape) and record the depth.

7. Note that if the electric water level indicator is used to determine depth of well, the offset distance between the tip of the probe and the electrode must be added to the reading to determine actual depth.
8. Withdraw the probe or tape.
9. Decontaminate the probe(s) and cable(s), in accordance with SOP 80.1.

3.3 DATA RECORDING AND MANIPULATION

Record the following information in the field logbook and appropriate sampling forms:

- Date and time;
- Weather;
- Method of measurement;
- Casing elevation;
- NAPL surface elevation = casing elevation - depth to NAPL;
- Apparent measured LNAPL thickness = depth to bottom of NAPL - depth to top of NAPL;
- Water level elevation = casing elevation - depth to water; and
- Well bottom elevation = casing elevation - depth to bottom (or read directly from tape).

4.0 CALIBRATION

No calibration is required. Ensure operability of electric water level indicator by testing sounder before use.

5.0 PRECAUTIONS

- Depending upon the device used, correction factors may be required for some measurements;
- Check instrument batteries before each use; and
- Exercise care not to break the seals at the top of the electric water level indicator probe.

STANDARD OPERATING PROCEDURE 40.3
SLUG TESTS

1.0 PURPOSE

The purpose of this standard operating procedure (SOP) is to provide information and technical guidance for performing falling- and rising-head *in situ* hydraulic conductivity tests and data analyses. The slug test method involves causing a sudden change in head in a control well and measuring the water level response within that control well. Head change may be induced by suddenly injecting into the well or removing from the well a known quantity of water, rapid removal of a mechanical "slug" from below the water level, increasing or decreasing the air pressure in the well casing, or emplacement of a mechanical slug into the water column.

The water level response in the well is a function of the mass of water in the well and the transmissivity and coefficient of storage of the aquifer. The results of the slug test may be used to determine an estimate of the hydraulic conductivity of the aquifer material near the well.

2.0 MATERIALS

- Work Plans;
- Field logbook;
- Well construction information and boring log;
- Photoionization detector (PID) or other monitoring instruments per site-specific health and safety plan;
- Decontamination equipment and supplies (SOP 80.1);
- Aquifer test data sheets;
- Personal protective equipment and clothing (PPE) per site-specific health and safety plan; and
- Slug-inducing equipment (solid slug, line, etc.) large enough to displace groundwater beyond the well filter pack.

3.0 PROCEDURE

Initially, an appropriate test methodology should be chosen. The selection of the appropriate test method (rising or falling head) is dependent primarily on saturated screen length, the well diameter, and the estimated hydraulic conductivity. If the screen extends above the water table, a rising-head test (water removal) should be used. The performance of a falling-head test (water added) in this circumstance would overstate the hydraulic conductivity value, as the measured response would reflect the equilibration rate of previously unsaturated material; unsaturated materials would equilibrate faster than saturated materials. When the measured water level in a monitoring well is above the screened portion of the well, a falling-head test methodology should be employed. A rising-head test may also be performed, but only if the initial water level reading (after the slug is removed) is above the screened interval.

For larger diameter and deeper wells, as a general rule and particularly for high conductivity materials, it is not feasible to remove a large enough slug or water volume to cause a sufficient change in head. In these cases the falling-head test method should be used.

It is recommended that a pressure transducer be used whenever possible to record water levels and time. A pressure transducer is required to record useful data when the hydraulic conductivity is high (greater than 10^{-3} cm/sec). The standard stopwatch and water-level indicator method is adequate for lower conductivity units.

The procedures outlined below assume use of a pressure transducer. Readings should be collected at intervals set on the data logger if used. If manual readings are collected, the following intervals should be applied:

- 0 to 5 minutes, every 10 seconds;
- 5 to 10 minutes, every 30 seconds;
- 10 to 30 minutes, every 1 minute; and
- 30 to 60 minutes, every 2 minutes.

3.1 Falling-Head Tests

1. Install pressure transducer near the total well depth and permit transducer and water levels to equilibrate to ambient conditions. Secure transducer cable to prevent movement during the test. Begin transducer readings.
2. Manually measure the static water level.
3. Insert slug completely below static water level or add a water "slug."
4. Intermittently measure water level and note the time of measurement with reference to the data logger.
5. Continue monitoring until water level is within 90% of the static level.

If a solid slug was used, stop the falling-head test recording at this point and begin a rising-head test by removing the solid slug from the well. If a solid slug was not used, simply end recording by the data logger at the completion of the falling-head test.

3.2 Rising-Head Tests

1. Install pressure transducer near the total well depth and permit transducer and water levels to equilibrate to ambient conditions. Secure transducer cable to prevent movement during testing.
2. Manually measure the static water level.
3. Remove sufficient volume of water to lower the water level a minimum of 1 ft below static water level, or
4. Install the solid slug fully below water level; permit static conditions to return and then remove the solid slug.
5. Begin readings with data logger.
6. Intermittently measure water level and note time of measurement with reference to data logger.
7. Continue monitoring until the water level is within 90% of the static level.

As a check on equipment operation and in the event that test data for a particular well are not usable, the data should be printed out in the field. If there is equipment failure (e.g., a non-attainment of a 1-foot minimum head change, unexplained fluctuations in water levels, etc.), the test can be rerun with minimum time lost.

The well numbers, static and subsequent water levels, programmed test numbers, and general comments should be recorded in the field notebook.

4.0 PRECAUTIONS

Not applicable.

Nguyen, V., G.F. Pinder. 1984. *Direct Calculation of Aquifer Parameters in Slug Test Analyses, Groundwater Hydraulics.* American Geophysical Union Water Resources Monograph 9 - This method can be applied to partially penetrating wells in both confined and unconfined aquifers it produces better values for low- to moderate-permeability materials.

STANDARD OPERATING PROCEDURE 50.1
SAMPLE LABELS

1.0 SCOPE AND APPLICATION

Every sample will have a sample label uniquely identifying the sampling point and analysis parameters. The purpose of this standard operating procedure (SOP) is to delineate protocols for the use of sample labels. An example label is included as Figure 50.1-A. Other formats with similar levels of detail are acceptable.

2.0 MATERIALS

- Sample label; and
- Indelible marker.

3.0 PROCEDURE

The use of preprinted sample labels is encouraged and should be requested from the analytical support laboratory during planning activities.
As each sample is collected, fill out a sample label ensuring the following information has been collected:

- Project name;
- Sample ID: enter the SWMU number and other pertinent information concerning where the sample was taken. This information should be included in site-specific work plan addenda;
- Date of sample collection;
- Time of sample collection;
- Initials of sampler(s);
- Analyses to be performed (NOTE: Due to number of analytes, details of analysis should be arranged with lab *a priori*); and
- Preservatives (water samples only).

Double-check the label information to make sure it is correct. Detach the label, remove the backing and apply the label to the sample container. Cover the label with clear tape, ensuring that the tape completely encircles the container.

4.0 MAINTENANCE

Not applicable.

5.0 PRECAUTIONS

None.

STANDARD OPERATING PROCEDURE 50.2
SAMPLE PACKAGING

1.0 SCOPE AND APPLICATION

The purpose of this standard operating procedure (SOP) is to delineate protocols for the packing and shipping of samples to the laboratory for analysis.

2.0 MATERIALS

- Waterproof coolers (hard plastic or metal);
- Metal cans with friction-seal lids (e.g., paint cans);
- Chain-of-custody forms;
- Chain-of-custody seals (optional);
- Packing material;
- Sample documentation;
- Ice;
- Plastic garbage bags;
- Clear Tape;
- Zip-top plastic bags; and
- Temperature blanks provided by laboratory for each shipment.

3.0 PROCEDURE

1. Check cap tightness and verify that clear tape covers label and encircles container.
2. Wrap sample container in bubble wrap or closed cell foam sheets. Samples may be enclosed in a secondary container consisting of a clear zip-top plastic bag. Sample containers must be positioned upright and in such a manner that they will not touch during shipment.
3. Place several layers of bubble wrap, or at least 1 in. of vermiculite on the bottom of the cooler. Line cooler with open garbage bag; place all the samples upright inside the garbage bag and tie.
4. Double bag and seal loose ice to prevent melting ice from soaking the packing material. Place the ice outside the garbage bags containing the samples.
5. Pack shipping containers with packing material (closed-cell foam, vermiculite, or bubble wrap). Place this packing material around the sample bottles or metal cans to avoid breakage during shipment.
6. A temperature blank (provided by laboratory) will be included in each shipping container to monitor the internal temperature. Samples should be cooled to 4 degrees C on ice immediately after sampling.
7. Enclose all sample documentation (i.e., Field Parameter Forms, Chain-of-Custody forms) in a waterproof plastic bag and tape the bag to the underside of the cooler lid. If more than one cooler is being used, each cooler will have its own documentation. Add the total number of shipping containers included in each shipment on the chain-of-custody form.

8. Seal the coolers with signed and dated custody seals so that if the cooler were opened, the custody seal would be broken. Place clear tape over the custody seal to prevent damage to the seal.
9. Tape the cooler shut with packing tape over the hinges and place tape over the cooler drain.
10. Ship all samples via overnight delivery on the same day they are collected if possible.

4.0 MAINTENANCE

Not applicable.

5.0 PRECAUTIONS

5.1 PERMISSIBLE PACKAGING MATERIALS

- Non-absorbent
  - — Bubble wrap; and
  - — Closed cell foam packing sheets.
- Absorbent
  - — Vermiculite.

5.2 NON-PERMISSIBLE PACKAGING MATERIALS

- Paper;
- Wood shavings (excelsior); and
- Cornstarch “peanuts”.

STANDARD OPERATING PROCEDURE 70.1
INVESTIGATION-DERIVED MATERIAL

1.0 SCOPE AND APPLICATION

Management of investigation-derived material (IDM) minimizes the potential for the spread of waste material onsite or offsite through investigation activities. The purpose of this standard operating procedure (SOP) is to provide general guidelines for appropriate management of potentially contaminated materials derived from the field investigations. Specific procedures related to the transportation and disposal of hazardous waste are beyond the scope of this SOP.

2.0 INTRODUCTION

Investigation derived material (IDM) consists of waste materials that are known or suspected to be contaminated with waste substances through the actions of sample collection or personnel and equipment decontamination. These materials include decontamination solutions, disposable equipment, drill cuttings and fluids, and water from groundwater monitoring well development and purging. To the extent possible, the site manager will attempt to minimize the generation of these materials through careful design of decontamination schemes and groundwater sampling programs. Testing conducted on soil and water investigation-derived material will show if they are also hazardous wastes as defined by RCRA. This will determine the proper handling and ultimate disposal requirements.

The criteria for designating a substance as hazardous waste according to RCRA is provided in 40 CFR 261.3. If IDM meet these criteria, RCRA requirements will be followed for packaging, labeling, transporting, storing, and record keeping as described in 40 CFR 262.34. Those materials that are judged potentially to meet the criteria for a regulated solid or hazardous waste will be placed in DOT-approved 55-gallon steel drums or another type of DOT approved container; based on waste characteristics and volume.

Investigation-derived material will be appropriately placed in containers, labeled, and tested to determine disposal options in accordance with RCRA regulations and Virginia Hazardous Waste Management Regulations.

3.0 INVESTIGATION-DERIVED MATERIAL MANAGEMENT

Procedures that minimize potential for the spread of waste material include minimizing the volume of material generated, material segregation, appropriate storage, and disposal according to RCRA requirements.

3.1 WASTE MINIMIZATION

In the development of work plan addenda, each aspect of the investigation will be reviewed to identify areas where excess waste generation can be eliminated. General procedures that will eliminate waste include avoidance of unnecessary exposure of materials to hazardous material and coordination of sampling schedules to avoid repetitious purging of wells and use of sampling equipment.

3.2 WASTE SEGREGATION

Waste accumulation and management procedures to be used depend upon the type of material generated. For this reason, IDM described below are segregated into separate 55-gallon storage drums or other appropriate DOT containers. Waste materials that are known to be free of potential hazardous waste contamination (such as broken sample bottles or equipment containers and wrappings) must be collected separately for disposal to municipal systems. Large plastic garbage or "lawn and leaf" bags are useful for collecting this trash. Even "clean" sample bottles or Tyvek should be disposed of with care. Although they are not legally a problem, if

they are discovered by the public they may cause concern. Therefore, items that are known to be free from contamination but are also known to represent "hazardous or toxic waste" to the public must not be disposed of in any public trash receptacle, such as found at your hotel or park.

3.2.1 Decontamination Solutions

Solutions considered investigation-derived materials range from detergents, organic solvents, and acids used to decontaminate small hand samplers to steam-cleaning rinsate used to wash drill rigs and other large equipment. These solutions are to be placed in 55-gallon drums with bolt-sealed lids or other appropriate DOT approved containers. Residual liquid IDM from decontamination pads will be removed and appropriately placed in container(s) at the end of each field day.

3.2.2 Soil Cuttings and Drilling Muds

Soil cuttings are solid to semi-solid soils generated during trenching activities or drilling for the collection of subsurface soil samples or the installation of monitoring wells. Depending on the type of drilling, drilling fluids known as "muds" may be used to remove soil cuttings. Drilling fluids flushed from the borehole must be directed into a settling section of a mud pit. This allows reuse of the decanted fluids after removal of the settled sediments. Drill cuttings, whether generated with or without drilling fluids, are to be removed with a flat-bottomed shovel and placed in 55-gallon drums with bolt-sealed lids or other appropriate DOT containers, as conditions or volume of IDM dictate.

3.2.3 Well Development and Purge Water

Well development and purge water is removed from monitoring wells to repair damage to the aquifer following well installation, obtain characteristic aquifer groundwater samples, or measure aquifer hydraulic properties. The volume of groundwater to be generated will determine the appropriate container to be used for accumulation of IDM.

For well development and purging, 55-gallon drums are typically an efficient container for accumulation. When larger volumes of water are removed from wells, such as when pumping tests are conducted, the use of large-volume portable tanks such as "Baker Tanks" should be considered for IDM accumulation.

Analytical data for groundwater samples associated with the well development and purge water will be used to assist in characterizing IDM and evaluating disposal options.

3.2.4 Personal Protective Equipment and Disposable Sampling Equipment

Personal protective equipment and clothing (PPE) may include such items as Tyvek coveralls, gloves, booties, and APR cartridges. Disposable sampling equipment may include such items as plastic sheeting, bailers, disposable filters, disposable tubing and paper towels. PPE and disposable sampling equipment that have or may have contacted contaminated media (soil, water, etc.) will be segregated and placed in 55-gallon drums separate from soil and water IDM. Disposition of this type of IDM will be determined by the results of IDM testing of the media in which the PPE and sampling equipment contacted.

3.3 MATERIAL ACCUMULATION

The IDM in containers must be placed in an appropriate designated RCRA container accumulation area at RFAAP, where it is permissible to accumulate such waste. IDM placed into a designated 90-day accumulation area will be properly sealed, labeled and covered. All drums will be placed on pallets.

A secure and controlled waste staging area will be designated by the installation prior the commencement of field sampling activities. Per the facility's requirements as a RCRA large quantity generator, waste accumulation cannot exceed 90 days for materials presumed or shown to be RCRA-designated hazardous wastes; waste which is known not to be RCRA-designated waste should be promptly disposed to municipal waste systems or appropriate facility.

3.3.1 IDM Accumulation Containers

Containers will be DOT-approved (DOT 17H 18/16GA OH unlined) open-head steel drums or other DOT approved container, as appropriate.

Container lids should lift completely off be secured by a bolt ring (for drum). Order enough containers to accumulate all streams of expected IDM including soil, PPE and disposable sampling equipment, decontamination water, purge water, etc.

Solid and liquid waste streams will not be mixed in a container. PPE and expendable sampling equipment will be segregated from other IDM and placed in different containers than soil. Containers inside containers are not permitted. PPE must be placed directly in a drum not in a plastic bag.

Pallets are often required to allow transport of filled drums to the staging area with a forklift. Normal pallets are 3×4 ft and will hold two to three 55-gallon drums depending on the filled weight. If pallets are required for drum transport or storage, field personnel are responsible for ensuring that the empty drums are placed on pallets before they are filled and that the lids are sealed on with the bolt-tighten ring after the drums are filled. Because the weight of one drum can exceed 500 lbs, under no circumstances should personnel attempt to move the drums by hand.

3.3.2 Container Labeling

Each container that is used to accumulate IDM will be appropriately labeled at the time of accumulation and assigned a unique identification number for tracking purposes. The following information will be written in permanent marker on a drum label affixed on the exterior side at a location at least two-thirds of the way up from the bottom of the drum.

- Facility name.
- Accumulation start date and completion date.
- Site identifier information (SWMU, boring, well, etc.).
- Description of IDM.
- Drum ID No.

4.0 MATERIAL CHARACTERIZATION AND DISPOSAL

IDM will be characterized and tested to determine whether it is a hazardous waste as defined by 40 CFR Part 261 and to determine what disposal options exist in accordance with RCRA regulations and the Virginia Hazardous Waste Management Regulations (VHWMR).

In general, IDM will be considered a hazardous waste if it contains a listed hazardous waste or if the IDM exhibits a characteristic of hazardous waste.

Work plan addenda will identify the appropriate characterization and testing program for IDM based on the following:

- Site-specific conditions related to chemicals of concern, etc.
- The nature and quantity of expected IDM to be generated during site-specific investigations.
- Applicable Federal, State, and local regulations, such as RCRA, VHWMR regulations and policies and procedures, and Army Regulation 200-1.
- RFAAP specific requirements and policies for IDM characterization and disposal at the time of the investigation.

In general, appropriate USEPA SW 846 Test Methods for Evaluating Solid Waste will be used for testing IDM and will be specified in work plan addenda. Other appropriate test methods may be specified by RFAAP in addition to SW 846 Methods that are specific to installation operations, the site of interest (percent explosive content, reactivity, etc.), or requirements for disposal at RFAAP water treatment facilities or publicly owned treatment works.

Responsibility for the final disposal of IDM will be determined before field activities are begun and will be described in work plan addenda. Off-site disposal of IDM will be coordinated with RFAAP (generator) to ensure appropriate disposition. The contractor will coordinate IDM transportation and disposal activities for RFAAP (generator).

At the direction of RFAAP, appropriate waste manifests will be prepared by the USACE contractor or Alliant Techsystems subcontractor for transportation and disposal. Alliant Techsystems or other appropriate RFAAP entity will be listed as the generator and an appointed representative from RFAAP will review and sign the manifest for offsite disposal.

RFAAP will make the final decision on the selection of the transporter, storage, and disposal facility (TSDFs) or recycling facility. RFAAP will provide the contractor a listing of previously used TSDFs for priority consideration. Proposed facilities that are not included on the listing are required to provide a copy of the TSDFs most recent state or federal inspection to the installation. Waste characterization and testing results will be submitted to RFAAP (generator) for review and approval before final disposition of the material.

Hazardous waste: Prior to final disposition, a hazardous waste manifest will be furnished by the TSDF to accompany transport to the disposal facility. Following final disposition, a certificate of disposal will be furnished by the disposal facility. Copies of the manifests and certificates of disposal are to be provided to RFAAP and retained on file by the contractor or subcontractor.

4.0 PRECAUTIONS

- Because the weight of one drum can exceed 500 lbs, under no circumstances should personnel attempt to move drums by hand.
- Refer to the site-specific health and safety plan when managing IDM.

5.0 REFERENCES

Safety Rules for Contractors and Subcontractors, (As Updated). Alliant Techsystems, Incorporated, Radford Army Ammunition Plant.

STANDARD OPERATING PROCEDURE 80.1
DECONTAMINATION

1.0 SCOPE AND APPLICATION

Before leaving the site, all personnel or equipment involved in intrusive sampling or having entered a hazardous waste site during intrusive sampling must be thoroughly decontaminated to prevent adverse health effects and minimize the spread of contamination. Equipment must be decontaminated between sites to preclude cross-contamination. Decontamination water will be free of contaminants as evidenced through either chemical analyses or certificates of analysis. This standard operating procedure (SOP) describes general decontamination requirements for site personnel and sampling equipment. Decontamination procedures for contaminants requiring a more stringent procedure, e.g., dioxins/furans, will be included in site-specific addenda.

2.0 MATERIALS

- Plastic sheeting, buckets or tubs, pressure sprayer, rinse bottles, and brushes;
- U.S. Army Corps of Engineers or installation approved decontamination water source;
- Deionized ultra-filtered, HPLC-grade organic free water (DIUF);
- Non-phosphate laboratory detergent;
- Nitric Acid, 0.1 Normal (N) solution;
- Pesticide-grade solvent, Methanol;
- Aluminum foil;
- Paper towels;
- Plastic garbage bags; and
- Appropriate containers for management of investigation-derived material (IDM).

3.0 PROCEDURE

3.1 SAMPLE BOTTLES

At the completion of each sampling activity the exterior surfaces of the sample bottles must be decontaminated as follows:

- Be sure that the bottle lids are on tight.
- Wipe the outside of the bottle with a paper towel to remove gross contamination.

3.2 PERSONNEL DECONTAMINATION

Review the site-specific health and safety plan for the appropriate decontamination procedures.

3.3 EQUIPMENT DECONTAMINATION

3.3.1 Drilling Rigs

Drilling rigs and associated equipment, such as augers, drill casing, rods, samplers, tools, recirculation tank, and water tank (inside and out), will be decontaminated before site entry, after over-the-road mobilization and immediately upon departure from a site after drilling a hole. Supplementary cleaning will be performed before site entry. There is a likelihood that contamination has accumulated on tires and as spatter or dust en route from one site to the next.

1. Place contaminated equipment in an enclosure designed to contain all decontamination residues (water, sludge, etc.).
2. Steam-clean equipment until all dirt, mud, grease, asphaltic, bituminous, or other encrusting coating materials (with the exception of manufacturer-applied paint) has been removed.
3. Water used will be taken from an approved source.
4. When cross-contamination from metals is a concern, rinse sampling components such as split spoons, geo-punch stems, and augers with nitric acid, 0.1N.
5. Rinse with DIUF water.
6. When semi-volatile and non-volatile organics may be present, rinse the sampling components with pesticide-grade solvent methanol.
7. Double rinse the sampling components with DIUF water.
8. Decontamination residues and fluids will be appropriately managed as IDM per work plan addenda and SOP 80.1.

3.3.2 Well Casing and Screen

Prior to use, well casing and screen materials will be decontaminated. This activity will be performed in the leak proof, decontamination pad, which will be constructed prior to commencement of the field investigation. The decontamination process will include:

- Steam cleaning with approved source water.
- Rinse with DUIF water.
- Air-dry on plastic sheeting.
- Wrap in plastic sheeting to prevent contamination during storage/transit.

3.3.3 Non Dedicated Submersible Pumps Used for Purging and Sampling

1. Scrub the exterior of the pump to remove gross (visible) contamination using appropriate brushes, approved water, and non-phosphate detergent (steam cleaning may be substituted for detergent scrub).
2. Pump an appropriate amount of laboratory detergent solution (minimum 10 gallons) to purge and clean the interior of the pump.
3. Rinse by pumping no less than 10 gallons of approved water to rinse.
4. Rinse the pump exterior with approved decontamination water.

5. When cross-contamination from metals is a concern, rinse the pump exterior with approved nitric acid 0.1N solution.
6. Rinse the pump exterior with DIUF water.
7. When semi-volatile and non-volatile organics may be present, rinse the pump exterior with pesticide-grade solvent methanol.
8. Double rinse the pump exterior with DIUF water.
9. Air-dry on aluminum foil or clean plastic sheeting.
10. Wrap pump in aluminum foil or clean plastic sheeting, or store in a clean, dedicated PVC or PTFE storage container.
11. Solutions and residuals generated from decontamination activities will be managed appropriately as IDM per work plan addenda and SOP 80.1.

3.3.4 Sample Equipment and Measuring Water Level Devices

1. Scrub the equipment to remove gross (visible) contamination using appropriate brush (es), approved water, and non-phosphate detergent.
2. Rinse with approved source water.
3. When cross-contamination from metals is a concern, rinse the sampling equipment with approved nitric acid 0.1N solution.
4. Rinse equipment with DIUF water.
5. When semi-volatile and non-volatile organics may be present, rinse the sampling equipment with pesticide-grade solvent methanol.
6. Double rinse the sampling equipment with DIUF water.
7. Air-dry on aluminum foil or clean plastic sheeting.
8. Wrap in aluminum foil, clean plastic sheeting, or zip top bag or store in a clean, dedicated PVC or PTFE storage container.
9. Solutions and residuals generated from decontamination activities will be managed appropriately as IDM per work plan addenda and SOP 80.1.

3.3.5 Other Sampling and Measurement Probes

Temperature, pH, conductivity, Redox, and dissolved oxygen probes will be decontaminated according to manufacturer's specifications. If no such specifications exist, remove gross contamination and triple-rinse probe with DIUF water.

4.0 PRECAUTIONS

- Manage IDM appropriately according to the requirements specified in work plan addenda.
- Follow appropriate procedures as specified in the site-specific health and safety plan.

STANDARD OPERATING PROCEDURE 90.1
PHOTOIONIZATION DETECTOR (HNu Model PI–101 and HW–101)

1.0 SCOPE AND APPLICATION

The purpose of this standard operating procedure (SOP) is to delineate protocols for field operations with a photoionization detector (HNu Systems Model PI–101 or HW–101). The photoionization detector (PID) detects total ionizables; hence it is used to monitor both organic and inorganic vapors and gases to determine relative concentrations of air contaminants. This information is used to establish level of protection and other control measures such as action levels. The PID cannot effectively detect compounds having ionization potentials above the photon energy level of the lamp used; therefore, methane, which has an ionization potential of 12.98 eV, is undetectable by PIDs because the lamps produce 9.5, 10.2, or 11.7 eV.

Use of brand names in this SOP is in not intended as an endorsement or mandate that a given brand be used. Alternate equivalent brands of detectors, sensors, meters, etc., are acceptable. If alternate equipment is to be used, the contractor shall provide applicable and comparable SOPs for its maintenance and calibration.

2.0 MATERIALS

- HNu Systems Model PI–101 or HW–101 survey probe with 9.5, 10.2, or 11.7 eV lamp;
- Lead-acid gel-cell battery;
- Calibration gas (e.g., isobutylene, 101 ppm) with regulator;
- Tygon tubing;
- Tedlar bag (optional);
- Instrument logbook; and
- Field logbook.

3.0 PROCEDURE

These procedures are to be followed when using the HNu in the field.

3.1 STARTUP

1. Before attaching the probe, check the function switch on the control panel to ensure that it is in the off position. Attach the probe by plugging it into the interface on the top of the readout module.
2. Turn the function switch to the battery check position. The needle on the meter should read within or above the green battery arc on the scale; if not, recharge the battery. If the red indicator light comes on, the battery needs recharging or service may be indicated.
3. Turn the function switch to any range setting. Listen for the hum of the fan motor. Check meter function by holding a solvent-based marker pen near the sample intake. If there is no needle deflection, look briefly into the end of the probe (no more than 1 or 2 sec) to see if the lamp is on; if it is on, it will give a purple glow. Do not stare into the probe any longer than 2 sec. Long-term exposure to UV light can damage the eyes. (See further information in Section 5.)
4. To zero the instrument, turn the function switch to the standby position and rotate the zero adjustment until the meter reads zero. A calibration gas is not needed since this is an electronic zero adjustment. If the span adjustment setting is changed after the zero is set, the zero should be rechecked and adjusted if

necessary. Allow the instrument to warm up for 3–5 min to ensure that the zero reading is stable. If necessary, readjust the zero.

3.2 OPERATIONAL CHECK

Follow the startup procedure in Section 3.1.

With the instrument set on the 0–20 range, hold a solvent-based marker near the probe tip. If the meter deflects upscale, the instrument is working.

3.3 FIELD CALIBRATION PROCEDURE

1. Follow the startup procedures in Section 3.1 and the operational check in Section 3.2.
2. Set the function switch to the range setting for the concentration of the calibration gas.
3. Attach a regulator HNu P/N 101-351 or equivalent (flow = 200 to 300 ml/min) to a disposable cylinder of isobutylene (HNu 101-351 or equivalent). Connect the regulator to the probe of the HNu with a piece of clean Tygon tubing. Turn on the valve of the regulator.
4. After 5 sec, adjust the span dial until the meter reading equals the benzene concentration of the calibration gas used, corrected to its equivalence, which should be marked on the canister (Isobutylene ~0.7X benzene).
5. Record in the field log the instrument ID No., serial No., initial and final span settings, date, time, location, concentration and type of calibration gas used, and the signature of the person who calibrated the instrument.
6. If the HNu does not function or calibrate properly, the project equipment manager is to be notified as soon as possible. Under no circumstances is work requiring monitoring with a PI–101 or HW–101 to be done with a malfunctioning instrument.

3.4 CALIBRATION TO A GAS OTHER THAN ISOBUTYLENE

The HNu may be calibrated to any certified calibration gas. However, after calibration, all subsequent instrument readings will be relative to the calibration gas used. General procedures include the following:

1. Calibrate according to procedure 3.3.
2. Partially fill and flush one-to-two times a gas bag (Tedlar recommended) with the certified National Institute of Standards and Technology (NIST) (formerly NBS) traceable calibration gas. Then fill the bag with 1–3 L of the calibration gas. If the gas is toxic, this must be done in a fume hood.
3. Feed the calibration gas into the probe with the range set for the value of the gas. After 5 sec, adjust the span control until the meter reads the value of the calibration gas.
4. Record the results of the calibration on the calibration/maintenance log and attach a new calibration sticker (if available) or correct the existing sticker to reflect the new calibration data. All subsequent readings will be relative to the new calibration gas.

3.5 OPERATION

1. Follow the startup procedure, operational check, and calibration check (refer to Section 3.1).
2. Set the function switch to the appropriate range. If the concentration of gas vapors is unknown, set the function switch to 0-20 ppm range. Adjust if necessary.
3. Prevent exposing the HNu to excessive moisture, dirt, or contaminant while monitoring the work activity as specified in the Site Health and Safety Plan.

4. When the activity is completed, or at the end of the day, carefully clean the outside of the HNu with a damp disposable towel to remove all visible dirt. Return the HNu to a secure area and place on charge. Charge after each use; the lead acid batteries cannot be ruined by over charging.
5. With the exception of the probe's inlet and exhaust, the HNu can be wrapped in clear plastic to prevent it from becoming contaminated and to prevent water from getting inside in the event of precipitation. If the instrument becomes contaminated, make sure to take necessary steps to decontaminate it. Call the Equipment Administrator if necessary; under no circumstances should an instrument be returned from the field in a contaminated condition.

4.0 MAINTENANCE

Calibration/maintenance logs are to be filled in completely whenever a PI-101 or HW-101 receives servicing. This is true of both contractor-owned and rental instruments.

The equipment manager should be called to arrange for a fresh instrument when necessary. The contractor's equipment facility is responsible for arranging all repairs that cannot be performed by the project equipment manager.

4.1 ROUTINE SERVICE

The PID's performance is affected by a number of factors. These include but are not limited to the decay of the UV lamp output over time and the accumulation of dust and other particulate material and contaminates on the lamp and in the ion chamber. Because of these factors, the PID should not be left in the field for a period of more than 2 weeks before being replaced with a fresh instrument. If a site is going to be inactive for a period of more than a week, all monitoring instruments are to be returned to the project equipment manager or his trained designee for servicing and/or reassignment. The following procedures are to be performed at the designated intervals for routine service.

Procedure	Frequency
Operational check	Before use and at instrument return
Field calibration	Before use and at instrument return
Full calibration	Bi-weekly (return instrument to equipment manager for replacement with a fresh unit)
Clean UV lamp and	Bi-weekly or as needed ion chamber
Replace UV Lamp	As needed

4.1.1 UV Lamp and Ion Chamber Cleaning

During periods of analyzer operation, dust and other foreign materials are drawn into the probe forming deposits on the surface of the UV lamp and in the ion chamber. This condition is indicated by meter readings that are low, erratic, unstable, non-repeatable, or drifting and show apparent moisture sensitivity. These deposits interfere with the ionization process and cause erroneous readings. Check for this condition regularly to ensure that the HNu is functioning properly. If the instrument is malfunctioning, call your equipment manager to arrange to have a fresh replacement.

4.1.2 Lamp eV Change

If different applications for the analyzer would require different eV lamps, separate probes, each with its own eV lamp, must be used. A single readout assembly will serve for any of the probes (9.5, 10.2, and 11.7 eV). A change in probe will require resetting of the zero control and recalibrating the instrument. The 11.7 eV

lamp will detect more compounds than either of the two lower eV lamps. However, the 11.7 eV probe needs more frequent calibration; it burns out much faster than the lower eV lamps.

5.0 PRECAUTIONS

- The HNu PI–101 and HW–101 are designed to sample air or vapors only. *Do not allow any liquids or low boiling vapors to get into the probe or meter assembly.*
- High concentrations of any gas can cause erroneous readings. High humidity can also cause the instrument readings to vary significantly from the actual concentration of gases or vapors present. This is true even through the HNu cannot react to water vapor.
- High humidity, dust, and exposure to concentrations of low boiling vapors will contaminate the ion chamber, causing a steady decrease in sensitivity.
- Continued exposure to ultraviolet light generated by the light source can be harmful to eyesight. If a visual check of the UV lamp is performed *do not look at the light source from a distance closer than 6 inches with unprotected eyes.* Use eye protection (UV-blocking sunglasses or safety glasses). Only look briefly—never more than about 2 sec.
- Place the instrument on charge after each use; the lead batteries cannot be ruined by over charging.
- If at any time the instrument does not check out or calibrate properly in the field, the equipment manager is to be notified immediately and a replacement obtained for the malfunctioning instrument. Under no circumstances should fieldwork requiring continuous air monitoring for organic vapors and/or gases be done with a malfunctioning Hnu or without a HNu or an approved comparable instrument.

PERMEABILITY TEST: FALLING HEAD - CONSTANT VOLUME U-TUBE

ASTM D 5084 - 90

Project No.: 31737767 BORING: QSB1 Test No.: P6781

Project Name: Radford Army Ammunition Plant SAMPLE: DEPTH (ft): 9.5-10

Specimen - Apparatus set-up - Test Information Cell No. H-1 Apparatus No. 3 Stage No.: 2

Preliminary Length/Area Calculations

Lo =	2.929	in	Lo=	7.439	cm
dLc=	0.041	in	Ao =	20.06	cm^2
Lc=	2.888	in	Vo =	149.19	cm^3
			Lc=	7.335	cm
dVc = 3 Vo * (dLc/Lo)			dVc=	6.27	cm^3
			Vc =	142.92	cm^3
Sc =	0.376	cm^{-1}	Ac=	19.487	cm^2

1) Specimen Tested in :	x	Triaxial Cell or		Compaction Mold or			
	x	with stones or		Stones with filter paper or			top + bottom
2) Specimen orientation for:	x	Vertical or		Horizontal permeability determination			
3) During saturation: Water flushed up sides of specimen to remove ai			x	No		Yes	
4) During consolidation:	x	Top and bottom drainage or		Top		Bottom only	
5) Direction of permeant :	x	Up during or		Down during permeation			
6) Permeant: water used	x	Tap		Distilled			
or		Demineralized		0.005 N calcium sulfate (CaSO4)			Permeability

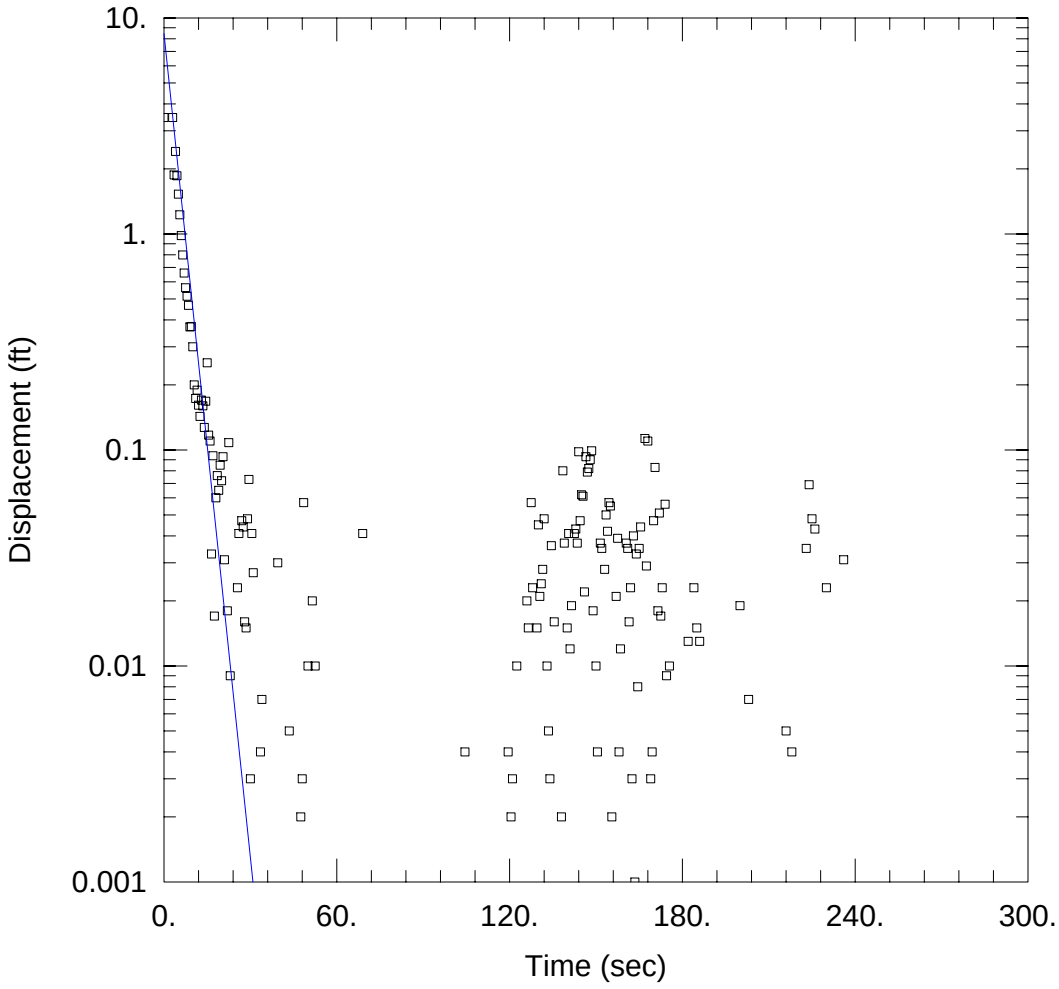
APPENDIX C.3

SLUG TEST DATA

THIS PAGE LEFT INTENTIONALLY BLANK



35MW1 RISING HEAD TEST

Data Set: P:\...\35MW1 Rising Head.aqt
Date: 04/03/08 Time: 08:43:05

PROJECT INFORMATION

Company: URS Corporation
Client: RFAAP
Project: 11656351
Test Location: Radford, VA
Test Well: 35MW1
Test Date: 3-19-08

AQUIFER DATA

Saturated Thickness: 30. ft Anisotropy Ratio (Kz/Kr): 1.

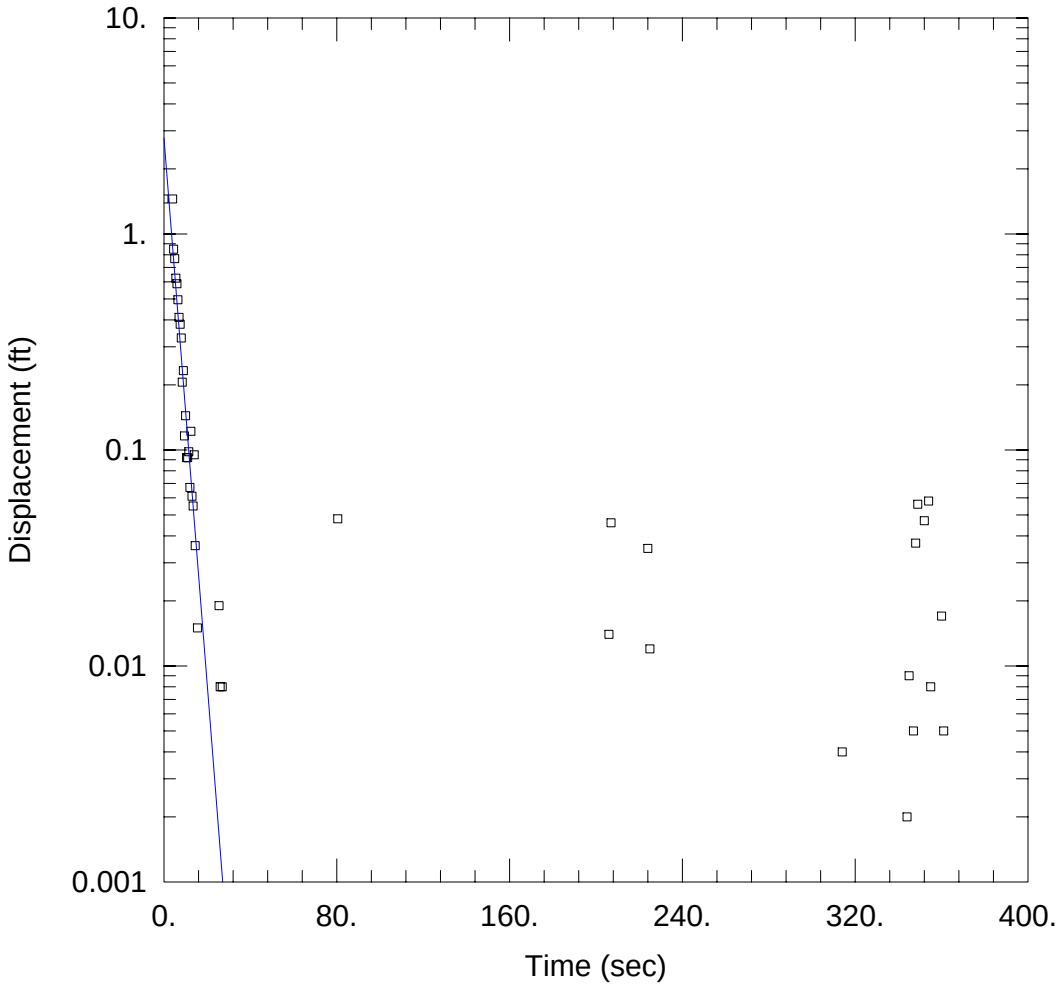
WELL DATA (35MW1)

Initial Displacement: 3.461 ft
Wellbore Radius: 0.083 ft
Screen Length: 25. ft
Gravel Pack Porosity: 0.2
Casing Radius: 0.083 ft
Well Skin Radius: 0.1875 ft
Total Well Penetration Depth: 14.08 ft

SOLUTION

Aquifer Model: Unconfined Solution Method: Bouwer-Rice

K = 0.004645 cm/sec y0 = 8.453 ft



35MW2 RISING HEAD

Data Set: P:\...\35MW2 Rising Head.aqt
Date: 04/03/08 Time: 08:45:11

PROJECT INFORMATION

Company: URS Corporation
Client: RFAAP
Project: 11656351
Test Location: Radford, VA
Test Well: 35MW2
Test Date: 3-18-08

AQUIFER DATA

Saturated Thickness: 30. ft Anisotropy Ratio (Kz/Kr): 1.

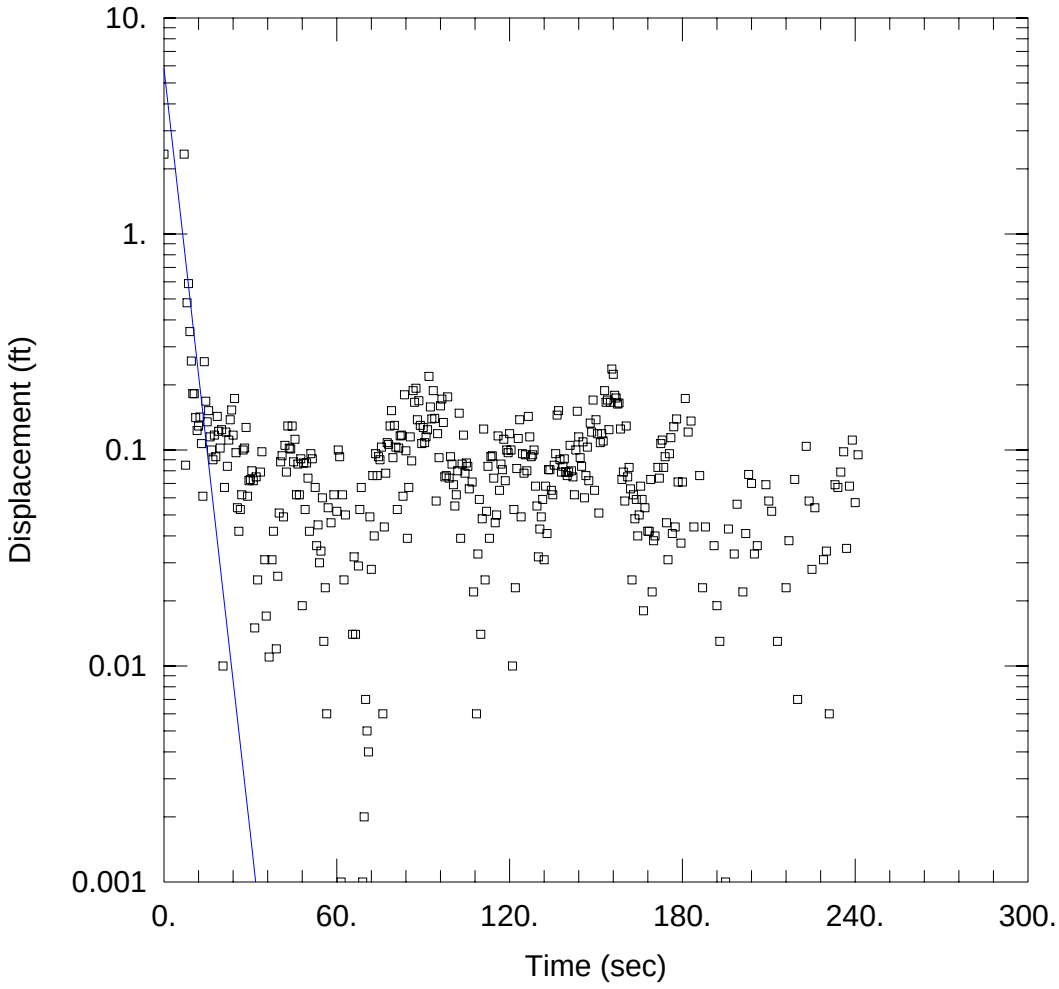
WELL DATA (35MW2)

Initial Displacement: 1.452 ft
Wellbore Radius: 0.083 ft
Screen Length: 20. ft
Gravel Pack Porosity: 0.2
Casing Radius: 0.083 ft
Well Skin Radius: 0.1875 ft
Total Well Penetration Depth: 11.8 ft

SOLUTION

Aquifer Model: Unconfined Solution Method: Bouwer-Rice

K = 0.005483 cm/sec y0 = 2.776 ft



35MW2 FALLING HEAD TEST

Data Set: P:\...\35MW2 Falling Head.aqt
Date: 04/03/08 Time: 08:43:50

PROJECT INFORMATION

Company: URS Corporation
Client: RFAAP
Project: 11656351
Test Location: Radford, VA
Test Well: 35MW2
Test Date: 3-18-08

AQUIFER DATA

Saturated Thickness: 30. ft Anisotropy Ratio (Kz/Kr): 1.

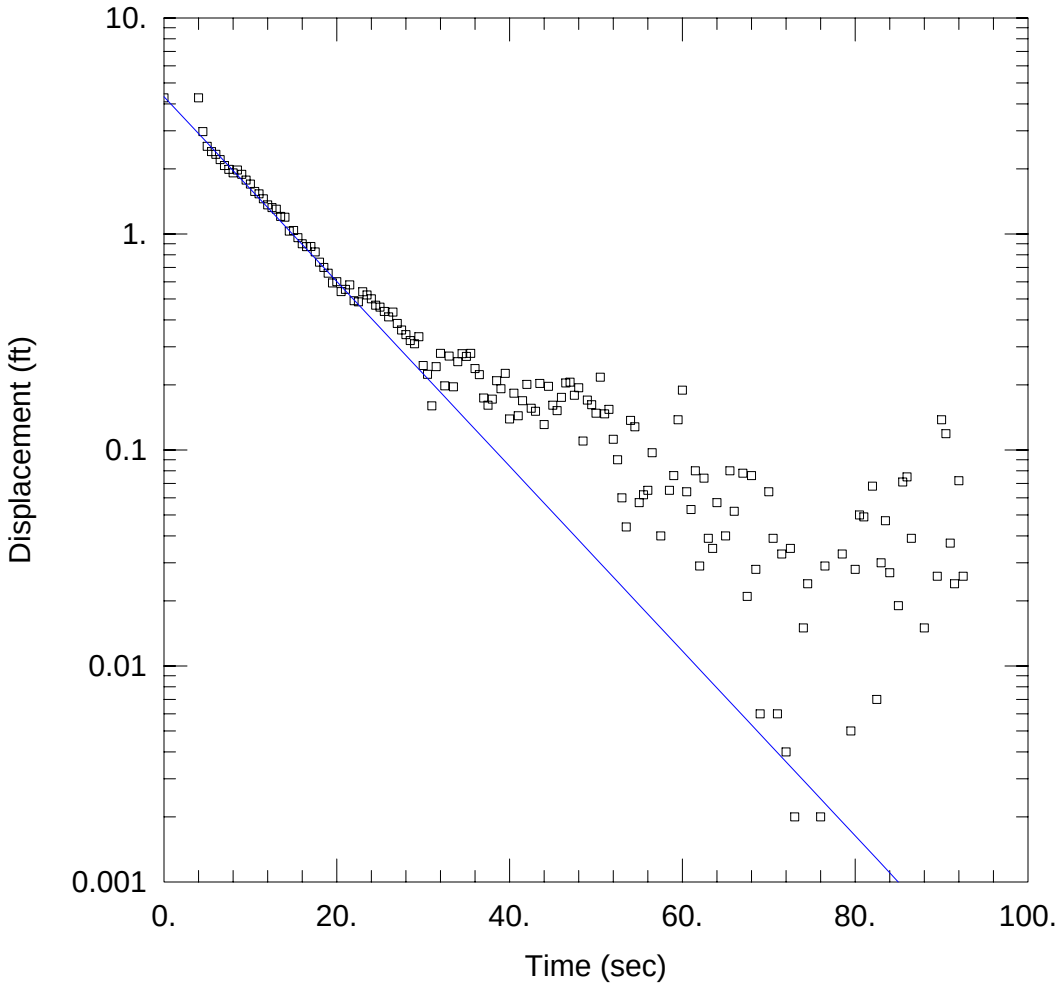
WELL DATA (35MW2)

Initial Displacement: 2.34 ft
Wellbore Radius: 0.083 ft
Screen Length: 20. ft
Gravel Pack Porosity: 0.2
Casing Radius: 0.083 ft
Well Skin Radius: 0.1875 ft
Total Well Penetration Depth: 11.8 ft

SOLUTION

Aquifer Model: Unconfined Solution Method: Bouwer-Rice

K = 0.005122 cm/sec y0 = 5.824 ft



37MW1 RISING HEAD TEST

Data Set: P:\...\37MW1 Rising Head.aqt
Date: 04/03/08 Time: 08:46:56

PROJECT INFORMATION

Company: URS Corporation
Client: RFAAP
Project: 11656351
Test Location: Radford, VA
Test Well: 37MW1
Test Date: 3-18-08

AQUIFER DATA

Saturated Thickness: 30. ft Anisotropy Ratio (Kz/Kr): 1.

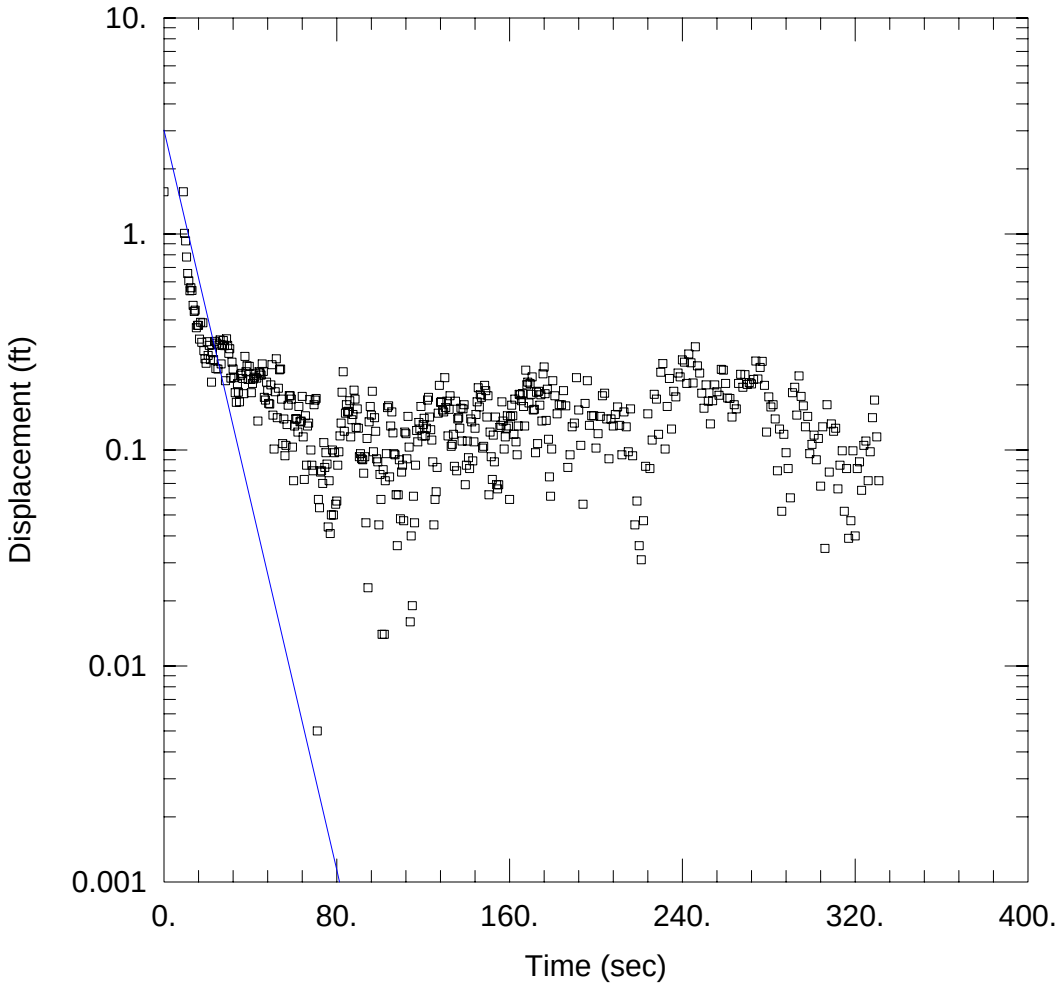
WELL DATA (37MW1)

Initial Displacement: 4.263 ft
Wellbore Radius: 0.083 ft
Screen Length: 25. ft
Gravel Pack Porosity: 0.2
Casing Radius: 0.083 ft
Well Skin Radius: 0.1875 ft
Total Well Penetration Depth: 10.35 ft

SOLUTION

Aquifer Model: Unconfined Solution Method: Bouwer-Rice

K = 0.00148 cm/sec y0 = 4.319 ft



37MW1 FALLING HEAD TEST

Data Set: P:\...\37MW1 Falling Head.aqt
Date: 04/03/08 Time: 08:46:04

PROJECT INFORMATION

Company: URS Corporation
Client: RFAAP
Project: 11656351
Test Location: Radford, VA
Test Well: 37MW1
Test Date: 3-18-08

AQUIFER DATA

Saturated Thickness: 30. ft Anisotropy Ratio (Kz/Kr): 1.

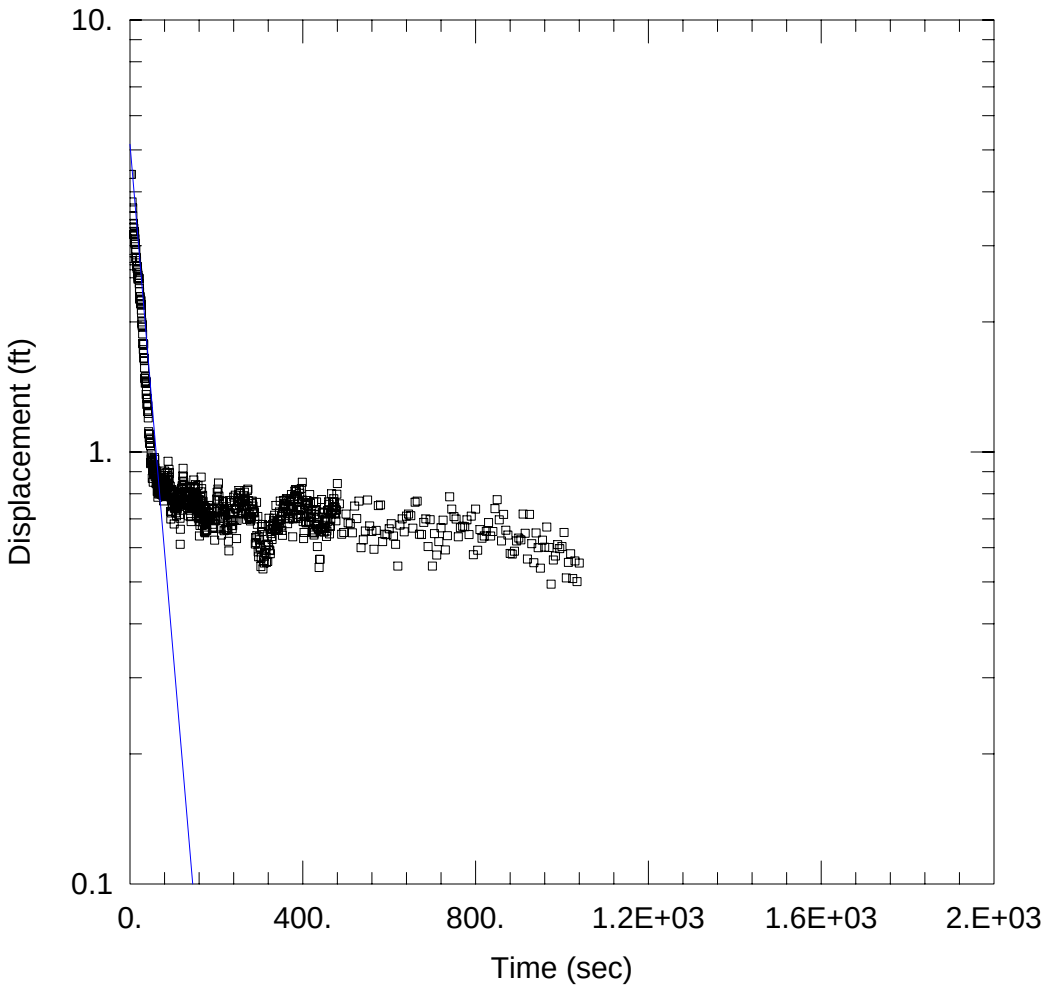
WELL DATA (37MW1)

Initial Displacement: 1.568 ft
Wellbore Radius: 0.083 ft
Screen Length: 25. ft
Gravel Pack Porosity: 0.2
Casing Radius: 0.083 ft
Well Skin Radius: 0.1875 ft
Total Well Penetration Depth: 10.35 ft

SOLUTION

Aquifer Model: Unconfined Solution Method: Bouwer-Rice

K = 0.001482 cm/sec y0 = 3.025 ft



37MW2 RISING HEAD TEST

Data Set: P:\...\37MW2 Rising Head.aqt
Date: 04/03/08 Time: 08:48:30

PROJECT INFORMATION

Company: URS Corporation
Client: RFAAP
Project: 11656351

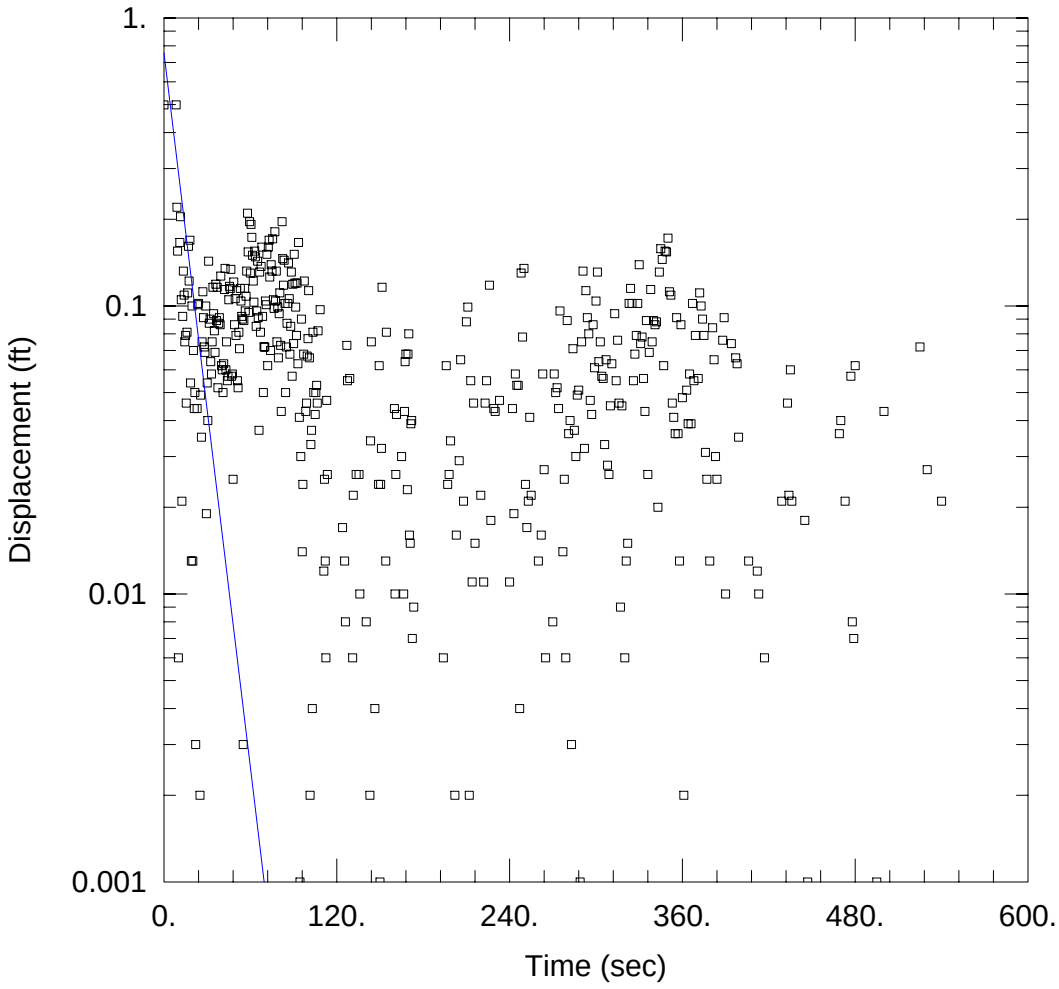
K = 0.002442 cm/sec y0 = 1.212 ft



38MW2 FALLING HEAD TEST

Data Set: P:\...\38MW2 Falling Head.aqt
Date: 04/03/08 Time: 08:52:36

PROJECT INFORMATION

Company: URS Corporation
Client: RFAAP
Project: 11656351
Test Location: Radford, VA
Test Well: 38MW2
Test Date: 3-18-08

AQUIFER DATA

Saturated Thickness: 30. ft Anisotropy Ratio (Kz/Kr): 1.

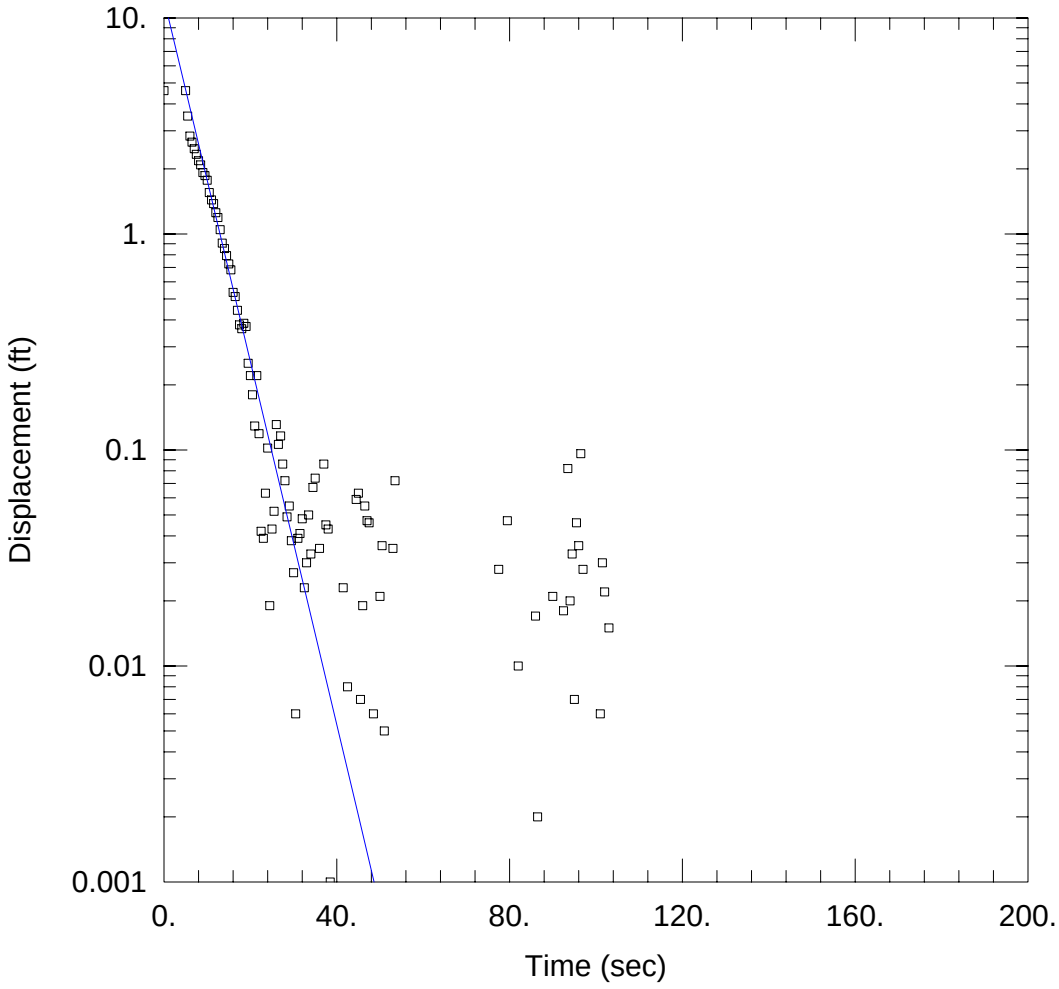
WELL DATA (38MW2)

Initial Displacement: 0.499 ft
Wellbore Radius: 0.083 ft
Screen Length: 20. ft
Gravel Pack Porosity: 0.2
Casing Radius: 0.083 ft
Well Skin Radius: 0.1875 ft
Total Well Penetration Depth: 11.61 ft

SOLUTION

Aquifer Model: Unconfined Solution Method: Bouwer-Rice

K = 0.001788 cm/sec y0 = 0.7548 ft



38MW3 RISING HEAD TEST

Data Set: P:\...\38MW3 Rising Head.aqt
Date: 04/03/08 Time: 08:56:17

PROJECT INFORMATION

Company: URS Corporation
Client: RFAAP
Project: 11656351
Test Location: Radford, VA
Test Well: 38MW3
Test Date: 3-18-08

AQUIFER DATA

Saturated Thickness: 30. ft Anisotropy Ratio (Kz/Kr): 1.

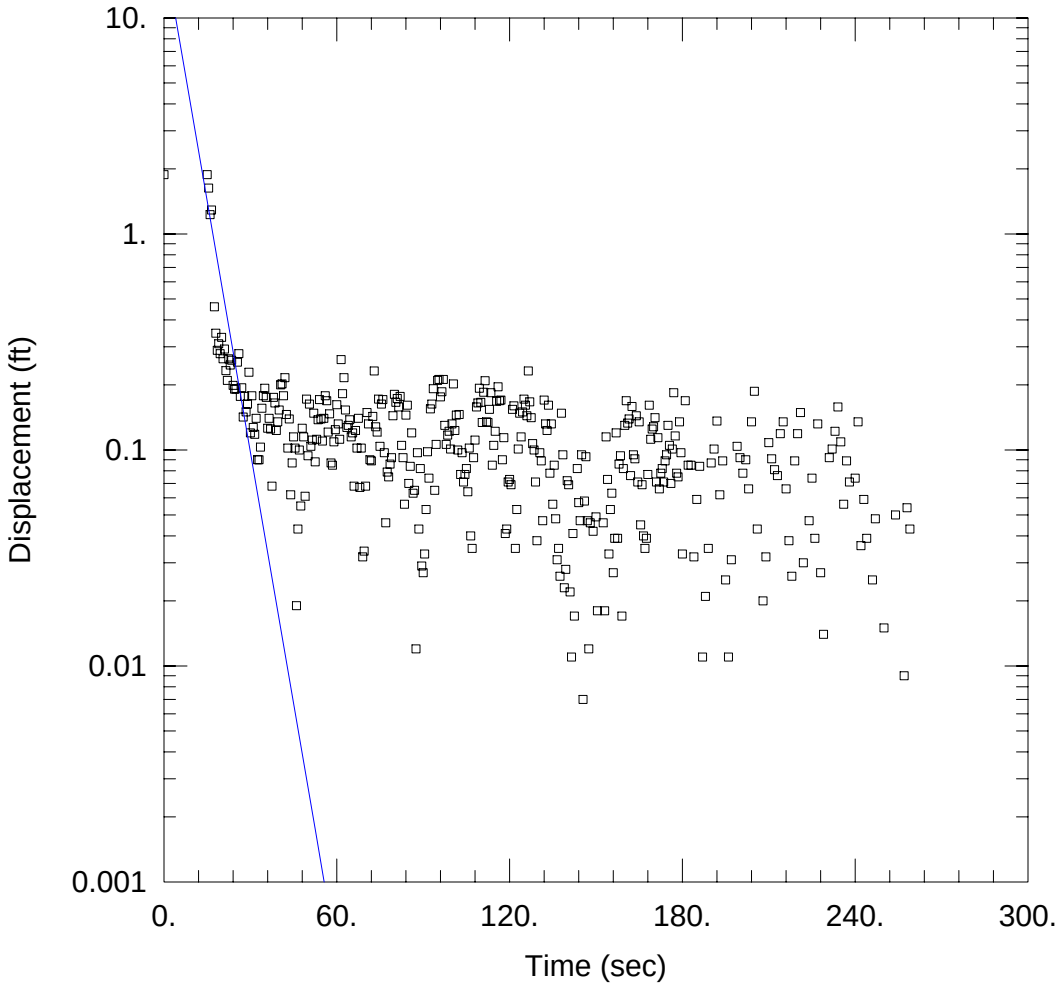
WELL DATA (38MW3)

Initial Displacement: 4.61 ft
Wellbore Radius: 0.083 ft
Screen Length: 25. ft
Gravel Pack Porosity: 0.2
Casing Radius: 0.083 ft
Well Skin Radius: 0.1875 ft
Total Well Penetration Depth: 17.17 ft

SOLUTION

Aquifer Model: Unconfined Solution Method: Bouwer-Rice

K = 0.003179 cm/sec y0 = 12.27 ft



38MW3 FALLING HEAD TEST

Data Set: P:\...\38MW3 Falling Head.aqt
Date: 04/03/08 Time: 08:55:18

PROJECT INFORMATION

Company: URS Corporation
Client: RFAAP
Project: 11656351
Test Location: Radford, VA
Test Well: 38MW3
Test Date: 3-18-08

AQUIFER DATA

Saturated Thickness: 30. ft Anisotropy Ratio (Kz/Kr): 1.

WELL DATA (38MW3)

Initial Displacement: 1.881 ft
Wellbore Radius: 0.083 ft
Screen Length: 25. ft
Gravel Pack Porosity: 0.2
Casing Radius: 0.083 ft
Well Skin Radius: 0.1875 ft
Total Well Penetration Depth: 17.17 ft

SOLUTION

Aquifer Model: Unconfined Solution Method: Bouwer-Rice

K = 0.002934 cm/sec y0 = 20.68 ft

Hydraulic Conductivity (K) Values

SWMU 35	Water Level	Screen Interval	Hydraulic Cond (cm/sec)	Hydraulic Cond (ft/day)	Test Used
35MW-1	1686.6	1692.72-1672.72	4.65E-03	13.17	rising head
35MW-2	1685.56	1692.91-1672.91	5.48E-03	15.54	rising head
D-2	1691.59	1692.41-1677.41	No Data	No Data	No Data
D-4	1691.88	1692.45-1677.45	2.80E-03	7.94	VI data
		Avg. Hyd. Cond.	4.31E-03	12.22	

SWMU 37, 38, Q	Water Level	Screen Interval	Hydraulic Cond (cm/sec)	Hydraulic Cond (ft/day)	Test Used
37MW-1	1683.41	1698.35-1673.35	1.48E-03	4.20	rising head
37MW-2	1688.96	1693.38-1673.38	5.37E-04	1.52	rising head
37MW-3	1685.04	1691.00-1671.00	5.27E-03	14.94	rising head
38MW-1	1682.75	1689.40-1669.40	1.64E-03	4.66	rising head
38MW-2	1683.17	1691.58-1671.58	2.44E-03	6.92	rising head
38MW-3	1682.74	1689.03-1669.03	3.18E-03	9.01	rising head
		Avg. Hyd. Cond.	2.43E-03	6.89	

Note:
Rising head slug test results were used where water level elevations were within the well screened interval. Falling head slug test results were used where water elevations were above the well screened interval.

Hydraulic Gradient (i) Calculations

Using Equation **i = dh/l**

i = hydraulic gradient
dh = difference in water column height
l = length or distance between measuring points

Use figure for line reference

SWMU 35	(l)	(dh)	(i)
Line A	281	6.32	0.022
Line B	266	6.00	0.023
		Avg Hyd Grd	0.023

SWMU 37, 38, Q	(l)	(dh)	(i)
Line A	182	5	0.027
Line B	49	3.92	0.080
Line C	225	2.5	0.011
Line D	120	0.42	0.004
		Avg Hyd Grd	0.031

Groundwater Flow Velocity (Vs)

Using Equation **$Vs = Ki/n_e$**

Vs = Groundwater Flow (seepage) Velocity (ft/day)
K = hydraulic conductivity (ft/day)
i = hydraulic gradient (ft/ft)
n_e = effective porosity (%)

Note:
Calculation assumes an estimated effective porosity of 0.30 percent for the Elbrook Formation

SWMU 35	(K)	(i)	(n_e)	(Vs) ft/day	(Vs) ft/year
Line A	12.22	0.022	0.30	0.9158	334.27
Line B	12.22	0.023	0.30	0.9185	335.24
			Avg. GW Flow Velocity	0.92	334.75

SWMU 37, 38, Q	(K)	(i)	(n_e)	(Vs) ft/day	(Vs) ft/year
Line A	6.89	0.027	0.30	0.6305	230.14
Line B	6.89	0.080	0.30	1.8361	670.17
Line C	6.89	0.011	0.30	0.2550	93.08
Line D	6.89	0.004	0.30	0.0803	29.32
			Avg. GW Flow Velocity	0.7005	255.68

Final Conductivity (µs): 1.14
Final DO: 5.40
Final Turbidity: 15.22 ntu
Final ORP: 139
Date Completed: 2/5/08
Well Locked At: 1230
Signature of Samplers:

Bailed about 15 gal with bailer prior to purging
Starting water depth = 29.74
Ended up with 1/2 drum purge water ≈ 25-30 gal

MONITORING WELL INSPECTION LOG

PROJECT NAME: RAAP 10 RFI /CMS

URS PROJECT NO. 11656351

FACILITY NAME: RFAAP - SWMU 38

MONITORING WELL: 38MW2

A. Inspected by (full name): Jim Carter

B. Date/Time of Inspection: 02-05-2008 @ 0800

C. Inspection Observations:

1. Locking protective casing:
   GOOD - NEW
2. Concrete well Pad:
   GOOD - NEW
3. Lock:
   GOOD - NEW
4. Erosion:
   NONE
5. Exterior well identification number:
   NEEDS ID NUMBER

D. Inspection Comments:

Notes:

CAS = Chemical Abstracts Service
mg/L = Milligram Per Liter
S.U. = Standard Units
TCLP = Toxicity Characteristic Leaching Procedure
VOC = Volatile Organic Compound
SVOC = Semi-volatile Organic Compound

MDL = Method Detection Limit
RL = Reporting Limit
LQ = Laboratory Qualifier
VQ = Validation Qualifier
r = Reason Code
NT = Not Tested

Data Qualifiers:
J = Analyte present. Reported value may not be accurate or precise.
U = Not detected. The associated number indicates the approximate sample concentration necessary to be detected.

= Concentration Above TCLP Regulatory Level (40 CFR Part 261)

Aroclor 1254 (ug/kg)

General Statistics

Number of Valid Data	16	Number of Detected Data	8
Number of Distinct Detected Data	7	Number of Non-Detect Data	8
		Percent Non-Detects	50.00%

Raw Statistics		**Log-transformed Statistics**	
Minimum Detected	17	Minimum Detected	2.833
Maximum Detected	1000	Maximum Detected	6.908
Mean of Detected	420.9	Mean of Detected	5.378
SD of Detected	405.6	SD of Detected	1.447
Minimum Non-Detect	5	Minimum Non-Detect	1.609
Maximum Non-Detect	5.3	Maximum Non-Detect	1.668

Note: Data have multiple DLs - Use of KM Method is recommended		Number treated as Non-Detect	8
For all methods (except KM, DL/2, and ROS Methods),		Number treated as Detected	8
Observations < Largest ND are treated as NDs		Single DL Non-Detect Percentage	50.00%

Warning: There are only 8 Detected Values in this data

Note: It should be noted that even though bootstrap may be performed on this data set

the resulting calculations may not be reliable enough tp draw conclusions

It is recommended to have 10-15 or more distinct observations for accurate and meaningful results.

Table D.2-2a
PROUCL 4.0 - Summary of Background vs Site Means Comparison - SWMU 37 Surface Soil
SWMUs 35, 37, 38, and AOC Q RFI Report
Radford Army Ammunition Plant, Radford, Virginia

Chemical	Is Site Data Distribution Normal?	Is Background Data Distibution Normal?	Means Test for Comparison	Background Comparison Results (Y/N)
Aluminum	Yes	No	Mann-Whitney	**Y**
Antimony	Yes	--	--	--
Arsenic	Yes	No	Mann-Whitney	N
Barium	Yes	Yes	Mann-Whitney**	N
Beryllium	Yes	No	Mann-Whitney	N
Cadmium	Yes	--	--	--
Calcium	Yes	No	Mann-Whitney	**Y**
Chromium	Yes	No	Mann-Whitney	**Y**
Cobalt	Yes	No	Mann-Whitney	N
Copper	Yes	No	Mann-Whitney	**Y**
Iron	Yes	No	Mann-Whitney	N
Lead	Yes	No	Mann-Whitney	N
Magnesium	Yes	No	Mann-Whitney	**Y**
Manganese	No	No	Mann-Whitney	N
Mercury	No	--	--	--
Nickel	No	No	Mann-Whitney	**Y**
Potassium	Yes	No	Mann-Whitney	**Y**
Selenium	Yes	--	--	--
Silver	Yes	--	--	--
Sodium	Yes	--	--	--
Thallium	Yes	--	--	--
Vanadium	No	No	Mann-Whitney	N
Zinc	Yes	No	Mann-Whitney	**Y**

Notes:
** Data set(s) included non-detects therefore Mann-Whitney test used
-- = Insufficient Detections to Determine Distribution
N = Site <= Background
Y = Site > Background

Assuming Normal Distribution		**Assuming Lognormal Distribution**	
95% Student's-t UCL	60.03	95% H-UCL	61.29
95% UCLs (Adjusted for Skewness)		95% Chebyshev (MVUE) UCL	67.57
95% Adjusted-CLT UCL	59.51	97.5% Chebyshev (MVUE) UCL	72.35
95% Modified-t UCL	59.97	99% Chebyshev (MVUE) UCL	81.73
Gamma Distribution Test		**Data Distribution**	
k star (bias corrected)	18.34	Data do not follow a Discernable Distribution (0.05)	
Theta Star	3.074		
nu star	1064		
Approximate Chi Square Value (.05)	989	**Nonparametric Statistics**	
Adjusted Level of Significance	0.0407	95% CLT UCL	59.91
Adjusted Chi Square Value	984.7	95% Jackknife UCL	60.03
		95% Standard Bootstrap UCL	59.76
Anderson-Darling Test Statistic	1.331	95% Bootstrap-t UCL	59.76
Anderson-Darling 5% Critical Value	0.744	95% Hall's Bootstrap UCL	59.52
Kolmogorov-Smirnov Test Statistic	0.178	95% Percentile Bootstrap UCL	59.79
Kolmogorov-Smirnov 5% Critical Value	0.162	95% BCA Bootstrap UCL	59.43
Data not Gamma Distributed at 5% Significance Level		95% Chebyshev(Mean, Sd) UCL	65.73
		97.5% Chebyshev(Mean, Sd) UCL	69.77
Assuming Gamma Distribution		99% Chebyshev(Mean, Sd) UCL	77.72
95% Approximate Gamma UCL	60.64		
95% Adjusted Gamma UCL	60.9		
Potential UCL to Use		Use 95% Student's-t UCL	60.03
		or 95% Modified-t UCL	59.97

Table D.3-1c
EPC Calculation Results - SWMU 38 Total Soil
ProUCL 4.0 for Full Data Sets
SWMUs 35, 37, 38, and AOC Q RFI Report
Radford Army Ammunition Plant, Radford, Virginia

Thallium (mg/kg)

General Statistics

Number of Valid Observations	29	Number of Distinct Observations	17

Raw Statistics		**Log-transformed Statistics**	
Minimum	0.1	Minimum of Log Data	-2.303
Maximum	0.25	Maximum of Log Data	-1.386
Mean	0.182	Mean of log Data	-1.734
Median	0.19	SD of log Data	0.265
SD	0.0451		
Coefficient of Variation	0.247		
Skewness	-0.152
